PROGRAM INFORMATION

All programs listed in BEEBUG magazine are produced direct from working programs. They are listed in LISTO1 format with a line length of 40. However, you do not need to enter the space after the line number when typing in programs, as this is only included to aid readability. The line length of 40 will help in checking programs listed on a 40 column screen.

Programs are checked against all standard Acorn systems (model B, B+, Master, Compact and Electron; Basic I and Basic II; ADFS, DFS and Cassette filing systems; and the Tube). We hope that the classification symbols for programs, and also reviews, will clarify matters with regard to compatibility. The complete set of icons is given

Editor's Jottings

PROGRAMMING IN C

This issue of BEEBUG sees the start of a series of introductory articles (four to five) which will be devoted to the programming language C. Given the amount of recent publicity with regard to this language, and its availability on the whole of the BBC micro range, including the Archimedes, this is perhaps no more than is reasonable. The object of this series is not to provide a comprehensive text book on C, but to provide a flavour of C for those who are considering this language as one which they might wish to use themselves.

In fact, this obscures a rather more fundamental question as far as BEEBUG is concerned. In all the time that we have been supporting the BBC micro (in its various guises), we have never devoted any part of the magazine to languages other than Basic and Assembler (unless in the form of reviews of compilers and interpreters for languages such as Forth, Prolog, Pascal, Comal, etc).

So the question is quite simple. Should BEEBUG, in the future, be prepared to devote further pages to articles about C and to programs written in C. If it were a matter of simply increasing the number of pages then the answer might be easier to find, but if that were the case then there might well be many other topics which might warrant some or better coverage in BEEBUG (hardware projects, for example). And any decision must be in the best interests of the majority of BEEBUG members.

If you have views on this subject then we would be pleased to hear from you (as we would on any topic related to the magazine). It is not our intention to initiate major changes, more to determine the direction which BEEBUG should take in the future.

LOOKING AHEAD WITH BEEBUG

The next issue of BEEBUG will mark the end of volume six, by which time we shall be looking forward to the first issue of volume seven. That will be a total of sixty issues of BEEBUG all told. As usual, we shall be publishing a complete index to the whole of volume 6, and this will be distributed free to all members with the first issue of volume 7 (the May issue).

..News..News..

MICROLINK FOR FREE

Anyone with a 1200/75 baud modem and telephone connection can try out Microlink's electronic mail service free of charge using Dial-a-Demo. Simply dial 01-583 1275 and when the >PAD prompt appears just key CALL 72 followed by Return. When asked to sign on, key ID MAG111 (that's three letters and three digits) and press Return again. The password DATABASE followed by Return will bring up the menu. There are four sections to browse through (communication, information, services and leisure) each describing a different aspect of the system. For further information telephone (0625) 878888.

ACCOUNTING FOR THE ARCHIMEDES

Minerva, of System Delta and System Gamma fame, has released an entire suite of five *Business Accounting* modules for the Archimedes. The programs are fully integrated with facilities for exporting data to spreadsheet and graphics programs. No price has yet been announced. Minerva are on (0392) 37756.

ARCHIMEDES OFF TO A FLYING START

Mitre Software is a company new to the Acorn world but already well established on PCs and compatibles. Now *Flying Start II*, a database package, is available for the Master 512 and for the Archimedes under the PC emulator, and a native mode version (for the Archimedes) is expected to be released shortly. *Flying Start* is a program which lets the user create records, files, lists, reports and labels for later retrieval and analysis quickly and easily. The package costs £69.95 (inc. VAT) for either system, and can be obtained from Mitre Software Ltd, International House, 26 Creechurch Lane, London EC3A 5BA or telephone 01-283 4646.

NEW GAMES FOR THE BEEB

New Games (or nearly new games) are still being released for the BBC micro. Bug-Byte's *Tutankhamun's Revenge* is described as an arcade adventure game allowing you, in the role of Howard Carter (the English explorer who discovered the tomb), to explore and collect treasure. A screen designer is also provided to

News..News..News..News..News..

add new rooms and pyramids to those already present. Cost of Tutankhamun's Revenge is £7.95 on dual 40/80 track disc. This new game follows Bug-Byte's release earlier this year of arcade adventure Plan B2, a sequel to the best selling Plan B. Plan B2 costs just £2.95 on cassette.

Play It Again Sam 2 from Superior Software is yet another games compilation featuring this time Repton 3, Galaforce, Codename:Droid and Craze Rider. Prices range from £9.95 for a dual cassette, through £11.95 for 5.25" disc to £14.95 for 3.5" disc. Bug-Byte are on 01-439 0666 and Superior are on (0532) 459453, or try your local Acorn dealer (BEEBUG keeps plenty of these in stock).

NO JACK OF ALL TRADES, BUT DABHAND AT SOME

Yet another new product from DABS Press has just been released in the form of *ViewSheet* and *ViewStore*, *A Dabhand Guide*. Written by Acorn User Editor Graham Bell, this mammoth 350 page tome offers to explain all you are ever likely to want to know about these two View family products for the BBC micro and Master. The book also contains listings of a number of utility programs designed to make use of ViewStore and ViewSheet even easier. The book costs just £12.95, from shops or direct from DABS Press, 76 Gardener Road, Prestwich, Manchester M25 7HU. Telephone 061-773 2413 for further information.

HELP FOR USERS

A new service aimed particularly at computer users, as opposed to programmers, has been established by *Micro Advisory Services* of Richmond, London. The intention is to help BBC micro users to exploit to the full the potential of their machines in serious and practical applications. If you are unsure as to the best

configuration, hardware or software combination, then Micro Advisory Services may be able to help. For more information telephone 01-878 7044 or write to the company at 314 Upper Richmond Road West, London SW14 7JN.

HIGH-RES GRAPHICS DUMP

Silicon Vision, producers of Real Time Graphics and Real Time Solids Modeller, has announced a new high resolution graphics dump for Epson compatible printers, called *Super-Dump*. This achieves a resolution of 1920x1024 (sic) on most printers. Like the high-res dump published in BEEBUG (Vol.6 No.6) this works from spooled files of VDU codes to achieve its aims. Silicon Vision are at 47 Dudley Gardens, Harrow, Middx HA2 0DQ, or telephone 01-422 2274.

POLYTECHNIC VIDEOTEX
DATABASE

Oxford Polytechnic is operating an educational Videotex service running at 1200/75 baud. The service offers information on staff research, educational telesoftware, curriculum development, primary education, applications for the disabled, plus news and comment on the Polytechnic world. The Videotex service can be accessed on Oxford (0865) 819937. For more information contact the Database Manager, Computer Education Unit,

Oxford Polytechnic, Lady Spencer-Churchill College,
Wheatley, Oxford OX9 1HX.

FIND OUT ABOUT BARTG

BARTG's (*British Amateur Radio Teleprinter Group*) latest quarterly journal (*Datcom*) has just been published. BARTG covers all aspects of amateur data communications (RTTY, Packet, Amtor and FAX) with UK membership costing £8. Members receive copies of *Datcom* four times a year. For more information contact John and Pat Beedie, GW6MOK and GW6MOJ, Ffynnonlas, Salem, Llandeilo, Dyfed SA19 7NP.

Geoff Bains casts an eye at Minerva's new package System Gamma for creating graphic displays from your database.

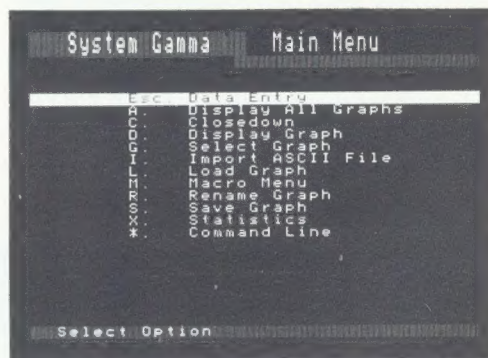

When Minerva launched the System Delta database language/package last year (see BEEBUG Vol.5 No.4) the one thing missing was a good way of displaying the data sorted and searched for. True, the data could be got at quite easily and used with a Basic program to draw a graph or chart. However, that relies on the same programming skills which System Delta was designed to render unnecessary. Now Minerva has followed the tradition of System Delta with a data presentation package called System Gamma.

Product System Gamma
Supplier Minerva Systems
 69 Sidwell Street,
 Exeter,
 Devon EX4 6PH.
 Tel. (0392) 377556
Price £49.95

Again the package is a programming language with a series of star commands to manipulate data and create displays on the screen. As with System Delta, when you purchase System Gamma you are not actually told how to use the programming language. It is not easy to guess it all either, as there are a great many star commands (such as *SGOPT, *SGdefine, *SGxscale, *SGfont, *SGaxis and *SGgraph), not to mention a myriad *FX163,18,n commands, which are near to impossible to fathom without help.

All the information to actually program your own graphics presentation package is contained in the System Gamma Programmer's Reference Guide. Unfortunately, as with System Delta before it, this will set you back a further £19.95.

I can't help feeling this is both a bit of a con and extremely silly. If the guide is written and printed, it costs very little more to include it (in presumably large quantities) with the software. This habit of Minerva's is not one we should look to encourage.

The documentation you do receive with System Gamma is the manual for an application already written. To be fair, this program does

allow you to present displays of data entered by hand or imported from ASCII files, or from System Delta, in just about any way you would want.

This program will suit the majority of people as it is. However, if you want to import data from something a little more exotic, you will have to write your own program or modify the ones given - and we are back to the Programmer's Reference Guide again.

System Gamma is supplied in a 32K EPROM which plugs into a normal 8/16K ROM socket thanks to a small carrier board of the Computer Concepts type. The ROM is compatible with all types of BBC micro but requires shadow RAM for extra memory and the Acornsoft GXR graphics extension ROM for some of its fill patterns. These can both be either built in from the start (as in the Master) or additional items to your model B micro.

selected colour and highlighted or not - the way the highlighting is done depends on the graph type but all are effective.

The type of graph is also specified on this table along with the font used for the axis and entry labels (normal, small or thin), and flags are provided to

Unfortunately, although the programming language is happy with, say, an Aries board for shadow RAM and a plug-in GXR ROM, some of the opening sections of the applications program are not - they require a little rejigging to get the program to run. It is not hard to do but rather defeats the purpose of ready-written software. In addition, the different on-screen fonts are not always available with a model B system.

display an outline, percentages, values and labels, and are toggled with Ctrl-letter keypresses. The whole table is easily and

The applications program provides graphics displays of any data in a number of different graph forms. These are simple histogram, '3D' histogram, pie chart, scatter diagram and line graph. The whole program is centered around a rather peculiar menu-and-additional-single-keypress driven module which will be a familiar style to existing Minerva software users.

quickly drawn up for any particular graph required. This data can then be saved to disc or altered with the simple and effective editor.

Data for the graphs is entered into a simple table providing for a label and two values for each entry. Each

entry's section of the resulting graph can now also be defined in a specified or automatically

Data can also be 'imported' into the program from other software (most likely a database or spreadsheet) as long as it is in an ASCII file and takes the form <label>, <x-value>, <y-value>, <label>, <x-value>, <y-value>, etc. Many programs can produce such data, and it is relatively simple to write a short Basic program to convert other

software's data to this format or to generate such data to start with. For System Delta data a

special program is provided for stripping the required data from the Delta index cards.

Once the data is entered it can be instantly displayed in the type of graph format chosen, and some further manipulation performed on the screen. The graph can be changed in size (and to some extent shape), and shifted around the screen. It can be printed out or the screen saved to disc for further additions later.

For graphs which plot two values for each entry (scatter and line, not histogram or pie) the line of best fit can be instantly plotted on the graph, and the equation is given on the prompt line at the bottom of the screen. Complete statistical analysis of each graph can also be performed by the program. The minimum, maximum, line of best fit, mean, standard deviation and correlation coefficient are also displayed nearly instantaneously and can be output to a printer if required.

Several graphs can be in memory at a time, and with more than one the ability to shrink graphs and move them around the screen becomes a vital one. More than one graph can be drawn on the same screen, at any size or relative position. Again, the multiple graph screen can be printed or saved to disc.

For that final touch of professional presentation, text can be added to the complete screen in any position inside boxes of various designs and in the same range of fonts as are provided for axis labelling. Lines can be drawn

to divide up the display and graphs boxed and shaded to give a professional look to the whole screen. Again the finished screen can be saved or printed.

Of course, the same set of instructions will often be used to produce similar graphs from different sets of data or to update a graph of cumulative data.

To make this much easier, System Gamma is also provided with a macro facility. All the operations of the system can be defined in a simple program (which basically uses the System Gamma star

command language, without the stars) and the program saved to disc.

Useful additions such as prompted waits for a keypress are included, so a complete 'slide show' presentation of many graphs can be put together for near-automatic display.

There is nothing that System Gamma does which any reasonably competent Basic programmer with a little elementary geometry couldn't manage on their own. However, this package does it all for you and at a

speed and with a flexibility which are hard to match.

The lack of inclusion of a real programmer's manual is a grave omission, but even without it System Gamma provides a powerful all-purpose data presentation package which will prove well worth the price to anyone struggling with the Beeb for business.

B

INSTANT LISTING OF FUNCTIONS AND PROCEDURES

Graham Crossley has developed a highly useful and practical utility which allows any function or procedure in your current program to be listed simply by referencing its name. Now you can forget all about line numbers.

INTRODUCTION

Several 'professional' computers allow function and procedure definitions within a program to be listed individually simply by typing the name of the required section of code after the LIST command. The utility presented here allows the BBC computer user to enjoy the same flexibility as those more expensive machines when editing and debugging a Basic program.

USING THE UTILITY

Type in the listing, taking particular care with the machine code, and then save it away before running it. If no errors are reported (the assembled code includes a checksum) you will be asked if the code is to be saved (using the name NEWLIST), after which the new list command is installed. At other times the file NEWLIST need only be *RUN to install the utility. In order to list a particular function or procedure in any program in memory simply type:

```
*LINE <fn/proc name> Return
```

and the desired section of code will be listed instantly. Function and procedure names may be abbreviated and ended with a full stop in which case the first function or procedure within the program whose name matches the characters entered will be listed. An error message is produced if the name entered cannot be found.

IMPROVEMENT

The best way to use a utility such as this, and the way that I use it, is to have it residing in sideways ROM or RAM along with other useful routines. This makes it permanently available

and immune from Break or Ctrl-Break. Details of how to achieve this can be found in the Advanced User guides. Articles describing the techniques involved have also been published in BEEBUG (see Vol.5 Nos.2-4 & Vol.6 No.1)

HOW IT WORKS

Use has been made of the *LINE operating system command which allows the user to pass a parameter string, in this case the name of a function or procedure, to a resident machine code routine. The call is vectored through the USERV vector at &200/201 the contents of which are changed to the address of the new list command. On entry the X and Y registers point to the address in memory of the parameter string.

A resident Basic program is searched for a DEF token (&DD) and a match check carried out between its name and the name entered at the keyboard. Should the names not match, the program is searched for the next DEF token. Assuming a match is found the line number is stored and the search continues, this time for the line where the function or procedure ends. This will be the occurrence of either:

1. ENDPROC.
2. End of function (=).
3. New DEF statement.
4. End of program.

The start and end line numbers of a desired function or procedure can easily be found, but the problem is how to pass these to the Basic interpreter along with the LIST command. The solution used here is to force the LIST command, together with start/end line numbers and Return, into the keyboard buffer as if they had been actually typed in. But what about the line numbers being in 2 byte format? These need to be converted to the normal decimal numbers that would normally be typed in at the keyboard. This is achieved by counting the number of 10000s, 1000s, 100s, 10s and 1s in the original two-byte number, converting the counts to ASCII codes (count OR &30) and placing them in the keyboard buffer. The conversion uses the subtraction method of counting and is actually used within the Basic ROM.

Continued on page 62

If programming in the language C has aroused your interest then our new series by Dec McSweeney starting this month could be just what you are looking for.

The language C has been around for some time now, available for "real computers" like the IBM, DEC and NCR ranges. Not having any of these beasts to hand, I was delighted to see several versions of the language become available for the humble Beeb. This article is the first in a series aimed at the experienced BBC Basic programmer who wants to get to grips with C. In the next few issues we will develop a number of programs which will illustrate the crucial differences between C and BBC Basic.

For more details, the reader is referred to "The C programming language" by Kernighan and Ritchie (reviewed elsewhere in this issue). This book is the standard work on the subject and was used in the preparation of this series. The review of Acornsoft C (BEEBUG Vol.6 No.5) contained background information about compiled languages, and C in particular, which I will not reproduce here.

Most of the information in this series applies to any implementation of C on any machine, though it is the BEEBUG version I have used to test out each program. To save space, examples of C statements are not usually presented in the context of a complete program, but if you have access to a C compiler try inserting the examples in this skeleton (note that C does not use line numbers):

```
/* skeleton program for C examples */
/* explanations later */
#include <h.stdio>
main() {
/* Insert main routines here */
}
```

```
/* Other functions follow */
```

A full explanation of the above follows the final example in this article. If you have the BEEBUG version of C, you will need to use a word processor to enter the programs. Some implementations include a built-in editor.

THE BASIC ELEMENTS

Let's look first at some general points regarding C syntax. A program in C consists of a set of functions; the top-level or harness function must be called **main**. The arguments or parameters of a function are enclosed in *normal* brackets (). Most C statements end with a semi-colon - exceptions you'll meet this month are the control flow statements **if** and **while** - and may be grouped together in braces { }. Comments reside between /* and */. Reserved words, that is words which are part of the C language, are written by convention in lower case.

VARIABLES

In C, as in Basic, data may be held in variables. The first major difference between C and Basic is that C requires the declaration of all variables before they are used. Rather than assuming the data type from the variable's name (e.g. integer%, string\$), the type must be declared, for example:

```
int number; /* integer - 16 bits */
char alpha; /* single byte (1 char)*/
float realnumber; /* 32 bits */
```

In the above, we have declared an integer called **number**, which can hold any value between -32768 and +32767; a single byte called **alpha**, which can hold any ASCII character; and a larger variable called **realnumber** with a capacity similar to Basic's real numbers. Much larger integers may be stored in type **long** (32 bits). This is not the whole story, but it's quite enough for now.

PROGRAM CONTROL

A program in C comprises a set of functions. All C programs must contain a function called `main()`; this may be the only

function in the program or it may call other functions, which call other functions in turn (or themselves, recursively), and so on. The language has no in-built facilities for input and output, but standard library functions are provided for such hardware-dependent activities (for example: `scanf()`, which is equivalent to INPUT, and `printf()`, the analogue of PRINT). The beginner may like to think of these as part of the language, as they are available universally.

As in Basic, control passes from one statement to the next in sequence, starting with the first statement in main. Naturally, there are a number of ways to disrupt this orderly flow, including `if` and `for`. There is also a `goto` statement, but don't let me catch you using it in such a structured language as C!

The `if` statement looks much like its Basic counterpart;

```
if (condition)
    statement-1;
else
    statement-2;
statement-3;
```

The condition in brackets is evaluated. If it is TRUE, statement-1 is executed; if it is FALSE, statement-2 is executed. In either case control then passes to statement-3. Several statements may be grouped together using braces, and multiple `if` statements may be nested. A simple example of an `if` might be:

```
byte = getchar();
if(byte >= 32)
    printf("printable");
else
    printf("control character");
```

`getchar()` is a library function returning a single character from the input stream, just as `GET$` does in Basic. The function `printf()` is like the

Basic PRINT statement, but rather too complicated to describe fully in one go. Bear with me.

FOR LOOPS

The `for` loop is also similar to the equivalent Basic construction. An example such as:

```
10 FOR N% = 29 TO 40 STEP 2
20 PRINT"Aargh!";
30 NEXT
```

could appear in C as:

```
int n;
for(n = 29; n <= 40; n = n+2)
    printf("Aargh!");
```

The bracketed expressions correspond to the start-value, end-value and step portions of the Basic FOR statement, but the loop is executed **while** the central expression (`n <= 40`) is true, and this need not relate to the variables in the start or end expressions. All three parts are optional. Note the absence of a NEXT statement. The loop consists of the statement following the `for`. However, several statements may be grouped in braces thus:

```
int n,n2;
for(n = 29 ; n <= 40 ; n = n+2) {
    n2 = n*n;
    printf("%d - Aargh!", n2);
}
```

The `printf` function is used in a more complex form here. The string (in quotes) contains formatting information about the variable list which follows; in this case `%d` specifies a decimal digit. Key in the above (inserting it into the **main** part of the skeleton program, say), and then try replacing the `%d` with `%o` (octal - base 8), `%h` (hexadecimal) or `%f` (floating point). You'd better change the declaration (`int n2;` to `float n2;`) for the last one.

WHILE LOOPS

Users of BBC Basic will be familiar with the REPEAT-UNTIL construction. The nearest equivalent in C is the `do-while` statement. An example:

```
10 N%=0
20 REPEAT
30 PRINT N%
40 N%=N%+1
50 UNTIL N%>10
```

which becomes in C:

```
int n = 0;
do{
printf("%d", n);
  n += 1;
}
while(n <= 10);
```

As you can see in this example, it is possible to assign values to variables when they are declared. The last statement, `n += 1`, is equivalent to `n = n+1`. This shorthand is available for all the arithmetic operators, '+', '-', '*', and '/', as well as others we have yet to meet. Again, note the use of braces to enclose the body of the loop. Note, too, the semicolon at the end of the while statement, which distinguishes the **do-while** from the true **while** described below. As with the Basic original, the loop is always executed at least once. Replace line 10 in the Basic program with:

```
10 N%=12
```

and the first line of the C example with:

```
int n = 12;
```

Despite the fact that `n` (or `N%`) starts off exceeding the terminating value, the loop is still executed once. If you want to avoid that possibility, then C offers an alternative form of the **while** as in the variation below. Examine this carefully and you'll see that the loop in the C program is never executed, because the test fails before the first pass through the loop.

```
/* This loop is never executed */
int n = 12;
while(n <= 10){
  printf("%d",n);
  n += 1;
}
```

Note the use of braces again to enclose the statements within the loop. **do-while** is exactly equivalent to REPEAT-UNTIL, but is less useful, and less frequently used than **while**.

Incrementing and decrementing counters is such a common activity in C that two special unary operators, `++` and `--`, have been provided. These can be used either before the variable (prefix) or after it (postfix), thus:

`while(n++ <= 10)` means 'test the value of `n`, then add 1 to `n`'.

`while(++n <= 10)` means 'add 1 to `n`, then test'.

Try using these constructions in the examples above. Here is another example, this time in the form of a complete program:

```
#include <h.stdio> /* compiler directive
                    - see below */

main()
{
  int n = 10;
  while(--n > 0)
  {
    printf("%d...", n);
  }
  printf("LIFTOFF!\n");
}
```

If you substitute `n--` for `--n` you'll once again see the difference between postfixing and prefixing the `++` operator.

FUNCTIONS

Functions in C are very like their equivalent in BBC Basic. Parameters, or arguments, are passed in brackets. The function itself uses *local* copies of the parameters ('call by value'), and returns a single value. The syntax might look confusing to a Basic programmer. A function like `printf()` may have many arguments, but returns a meaningless value, while `getchar()` has no arguments though the brackets are still needed, returning a single character. A function is assumed to return an integer unless declared otherwise.

Variables declared external to a function may be changed from within a function by passing a pointer to the variable rather than the variable itself -

similar to the idea of passing an address to a Basic function. Pointers are an important feature of C, and we'll cover them in detail later.

To close this introduction and illustrate the points covered, we will now write a program to calculate and print the square and square root of a number entered by the user.

```
/* c.sqrt calculate the square and */
/*      square root of a number */

#include <h.stdio>
main()
{
    double n;
    double sqrt();
    n=0;
    printf("give me a number; ");
    scanf("%f", &n);
    printf("You entered %3.0f", n);
    printf(" square = %5.0f", n*n);
    printf(" root = %2.4f \n", sqrt(n));
}

double sqrt(num)
double num;
{
    double wrk,ans;
    wrk=ans=num/2.0;
    while(wrk > 0.001)
    {
        ans=(ans+(num/ans))/2.0;
        wrk=( (num/ans)-ans);
        if(wrk<0.0)
        {
            wrk *= -1.0;
        }
    }
    return(ans);
}
```

The first two lines are comments; the next is a compiler directive, which tells the compiler to copy in a file called `h.stdio` (supplied with

Beebug C). This contains the input-output routines we will be using. Then comes our main routine, in which we declare our variable `n` and our function `sqrt()` as type **double** (for double precision), print a message, accept a number and call the `sqrt` function. Note the declaration of the function `sqrt` as type **double**. This is necessary because a function is assumed to return an integer unless otherwise specified.

The function `scanf()` returns the number entered by the user. This function resembles **INPUT** in the same way that `printf()` resembles **PRINT**, and the arguments are analogous - first a control string, then a list of variables. The argument specifying the destination, `&n`, is actually a pointer to the receiving variable. This is always so with `scanf()` - and a common source of program errors!

Three calls to `printf()` follow, showing how an expression like `n*n` or a function returning a value may replace a variable of the same type (this is generally true throughout the language). The `\n` in the control string causes a newline character to be printed.

After the brace terminating `main()`, the `sqrt` function is defined. This has an argument, locally known as `num`, which must be specified outside the function braces `{}`. Within the braces we define our local variables. The actual computation is an iteration, and the limit of accuracy is plus or minus 0.001. Think of the `while` loop as a **REPEAT-UNTIL** construction, and the logic is easier to follow. The `return()` statement at the bottom of the function specifies the value passed back to `main` just like the terminating `=` of a BBC Basic function.

As it stands, the program will run once and stop. See if you can tweak it to loop until the user enters 0, or to deliver the square roots of a range of numbers (hint: use a `for` loop, or `while(n++<100)`).

Swots among you might like to validate the input, which must of course be positive. C you next month!

B

THE C PROGRAMMING LANGUAGE

This month we commence a short series on programming in the language 'C'. Anyone who wishes to pursue C more seriously will need an adequate reference, and the book most often recommended is 'The C Programming Language' by B.W.Kernighan and D.M.Ritchie. Ray Hughes gives a run down of what you can expect to find in this acclaimed book.

THE C PROGRAMMING LANGUAGE

by B.W.Kernighan & D.M.Ritchie
published by Prentice Hall
at £23.95 (£22.75 to BEEBUG members).

This is an excellent introduction to the world of C programming, containing 228 pages of highly readable information laid out in several distinct sections.

A TUTORIAL

This is included to enable programmers new to C to pick up the language as quickly as possible. However, as the book says, it is not a beginner's guide to programming, and its readers are expected to understand already such concepts as variables, assignments, loops and functions etc. It gets into coding straight away with a good old "Hello world" type program, which is probably the first piece of code written in any language by first time users. Throughout the book, there are also question and answer sessions to allow the reader to fully check that he/she understands the current chapter before moving on to the next. The tutorial in its 30 odd pages manages to cover the main core of the language.

LANGUAGE & PROGRAM STRUCTURE

This section of the book deals with the more complex ideas that need to be covered for a full understanding of the facilities that can be made available to the C programmer. This is in fact the main body of the book and covers in order the following topics:

Types, Operations and Expressions
(Char, int, float, short, long, double etc)

Control Flow
(While, wend, for, next, do-while, case, etc)

Functions and Program Structure
(main() recursion, macros etc)

Pointers and Arrays
(pointers, multi-dimensional arrays etc)

Structures
(lookup tables, fields, Unions etc)

Input/Output
(getchar, putchar, scanf, file access etc)

This then ends the main body of the book. However, the last 85 pages cover other aspects of the language that serious users will want to know about. There is a special chapter on the UNIX system interface, but this may not be of much use to Acorn machine owners, except those lucky Archie owners who may one day get access to UNIX via the proposed ARX operating system.

Next there is the C reference manual which is a full and concise description of all keywords etc, with brief examples of their use. Finally, we have an excellent index covering all items mentioned in the preceding pages.

Throughout the book the authors describe and recommend standard programming techniques, and extensive use is made of examples to demonstrate, in particular, structured programming methods. Many short, and some not so short programs are listed in the book, many of which I am sure budding programmers will take and later modify to their own requirements.

IN CONCLUSION

Although reviewed many times since it was first published in 1978, this may be the first review of K&R read by many BEEBUG readers, since C has only recently been released for the Acorn machines. Now nearly a decade old, this book has remained throughout that time the most important reference work for C programmers. It has no equal in what it attempts to achieve, or the deceptive ease with which this is accomplished.

Both the Acorn and BEEBUG implementations of C refer the reader to Kernighan & Ritchie for a detailed guide to the C language. It is certainly not a cheap book (although BEEBUG members are entitled to the usual discount), and compared to some language manuals seems quite thin at 228 pages. However, the information contained within those pages is excellent, and the book really should be considered an absolute must by any prospective C programmer who wants to exploit the language fully.

B

Cocktail of 3D Procedures

If you have ever wanted to produce 3D wire frame graphics this program is for you. David Lowndes Williams offers procedures to create the 3D equivalents of Basic's DRAW and MOVE instructions.

Two procedures `PROCmove(x,y,z)` and `PROCdraw(x,y,z)` form the basis of this article, and provide the 3D equivalents of the `MOVE x,y` and `DRAW x,y` commands in Basic. In order to explain how they work the chosen 3D coordinate system needs explaining. Figure 1 shows that the *x* and *y*-axes are exactly as they are normally, i.e. in the plane of the screen. The *z*-axis is perpendicular to the screen, i.e. it appears to go into and out of the screen. Representing 3D points correctly on the 2D screen involves some extensive arithmetic in order to convert each point (*x,y,z*) to a point (*x,y*). The procedures take away this drudgery by performing all the calculations necessary.

Figure 1

I suggest at this stage, that you type in and run the demonstration program. This draws a 3D wire-frame projection of a wine glass sitting on a grid, with an umbrella in it. The program can be made to view the wine glass from any angle, and accounts for perspective as well. Lines 1000-1280 contain all the routines that you need

to use `PROCmove` and `PROCdraw`. Removing line 1150 will remove perspective, giving a true isometric representation of the object.

EXPLAINING THE DEMONSTRATION PROGRAM

Before `PROCmove` and `PROCdraw` can be used to display the object, `PROCinitrotation(x,y,z)` must be called (see line 110), the parameters representing the orientation of the object. The easiest way to understand this is to run the demonstration program, and try changing the values. For example, start with `PROCinitrotation(0,0,90)` and you will see the glass standing upright on its base grid. The reason why the object needs to be rotated by 90 degrees about the *z* axis to bring it upright, is because this makes it easier to determine the coordinates in the position (0,0,0). Now try `PROCinitrotation(0,45,90)` which means "display the object rotated 45 degrees about the *y*-axis". You will now see the glass standing on a rotated grid. If you want to look down on the glass you should try rotating about the *x*-axis by 90 degrees ie `90,0,90`. Try it; the base will be closest to you. Using `-90,0,90` puts the umbrella closest to you. Negative values rotate the object in the opposite direction. These last two sets of values give a superb demonstration of perspective. You should also try them with `PROCperspective` in line 1150 removed.

OPERATION OF THE PROCEDURES

`PROCmove(x,y,z)` and `PROCdraw(x,y,z)` work in a similar fashion to the standard `MOVE` and `DRAW` commands, but in '3 dimensions'. The apparent position of a 3D point on the screen depends on the rotation set up in `PROCinitrotation(x,y,z)`, and the perspective setting. `PROCrotate`, which is called by `PROCmove` and `PROCdraw`, calls `PROCperspective(S)` at line 1150 where *S* is the size of the image on the screen (try values from 300-800 for most objects). In the example, *S* is set to 700 at line 110.

I suggest that when drawing your own 3D designs you initially remove the call to `PROCperspective`, and only insert it when your design is completed. Your drawing will still look presentable, even if it is not truly in

perspective. You will probably find it helpful to sketch your object on paper first - isometric graph paper is a great help here.

When designing your own programs using these procedures, note that the following variables are used by the procedures:

k m n o p q r s t u v w x y z

and your programs should not alter them. It is particularly easy to forget and use the variables x, y or z in your program.

To summarise, just set S to establish the size of your object, call PROCinitrotation to set its starting position and from then on use PROCmove, and PROCdraw to plot it out. Delete PROCperspective at line 1150 if perspective is not required, and steer clear of variables k-z. All the other procedures look after themselves.

TECHNICAL NOTES - THE PROCEDURES

The program uses the matrix method to perform the rotation. Assuming we are rotating the vector

$\begin{pmatrix} x \\ y \end{pmatrix}$ by an angle of A degrees, then:

$$\begin{pmatrix} x \\ y \end{pmatrix} \begin{pmatrix} \cos A & -\sin A \\ \sin A & \cos A \end{pmatrix} = \begin{pmatrix} \text{new } x \\ \text{new } y \end{pmatrix}$$

$$\begin{aligned} \text{i.e. new } x &= x * \cos A + y * -\sin A \\ \text{new } y &= x * \sin A + y * \cos A \end{aligned}$$

It is unnecessary to calculate the sines and cosines of A repeatedly: we get PROCinitrotate to do this at the beginning, and store the results

in variables k to s. To perform a rotation, it is then a simple matter of adding the results of two multiplications. This is done by PROCrotate.

Perspective is catered for by remembering that the z axis is perpendicular to the plane of the screen. Therefore dividing each x and y coordinate by z, and applying a scale factor S, the image will be foreshortened appropriately depending on whether z is large or small. To overcome the possibility of z being zero, and hence a division by zero error occurring, z has 1000 added to it before the scaling takes place.

Having called PROCperspective, 640 is added to the x, and 512 to the y co-ordinates to put the model at the centre of the screen.

TECHNICAL NOTES - THE MAIN PROGRAM

The main program to draw the cocktail glass, base and umbrella, lies between lines 120 and 320. It uses PROCmove and PROCdraw, after issuing a PROCinitrotation. The loop from line 180 to 280 calculates points along the vertical lines of the wine glass. Other loops draw a circle at the top and bottom of the wine glass, and an umbrella.

PROGRAMMING YOUR OWN 3D DISPLAY

If you wish to provide the code for your own object, lines 110 to 330 will need to be replaced. A suitable example to try yourself is that of the house shown in figure 2, listing 1 is the resulting code. You will need a reasonably good 3D eye for this. but I have kept it simple

by placing the base of the house on the x-z plane, allowing many of the y coordinates to be zero. Having decided on the coordinates of each of the points, all that remains is to draw them in the right order. There are many ways to do this, the one shown in listing 1 is almost certainly not the one taking the least moves. Start by loading the wine glass program and delete lines 110 to 340 inclusive. Now add the lines given in listing 1. The missing line numbers are for the insertion of the rotation routine discussed later.

Figure 2

Remember that you must not use the variables k and m - z. Instead, the program uses xx, yy and zz, setting their sizes in line 90. The program also starts with PROCrotation(0,0,0) to keep the image exactly as shown in figure 2. You may like to put the house-drawing routine in a loop with say sx, sy and sz changing by 5 degrees each time:

```
130 FOR sx=0 TO 360 STEP 5
140 sz=sx:sy=sx
150 CLS
160 PROCinitrotation(sx,sy,sz)

.

420 Q=INKEY(50)
430 NEXT
```

I hope that this article provides the basis for your own 3D displays. Having experimented you may like to provide procedures that translate (shift the position of the whole image), and perhaps shear (scale the coordinates relative to their position).

VIDEO CATALOGUER

Tired of keeping track of the contents of all your video cassettes? Let the computer take the strain with Keith Sumner's cataloguing program.

This is a novel database application program which allows the user to keep track of what is on each video tape, where on the tape each item is, and how much time remains. The program is menu driven, allowing the standard database manipulations of loading, data entry, editing, searching, browsing, sorting, deleting and saving, and will also print a label for any selected cassette.

The program is being published in two parts. In this issue we will provide the essential facilities such as the loading, saving, and editing of video cassette information. Next month we will continue with the routines which will allow records to be sorted and a hard copy and cassette labels to be printed.

The program should first be typed in and saved to disc or tape. When run, the program presents the user with a series of options (eleven in total) together with some program status information. Each of the possible options is discussed below. The first time you run the program you will have no data file to load, so the only options available to you will be 'data entry' and 'exit'. If you have the magazine tape or disc, you can load an example file called VIDDAT using the menu option 0 (load data).

OPTION 0 - DATA LOADING

Enter the name of a previously created file to be loaded. If data is already present in memory a warning is given before the loading operation is allowed to continue. If the program is to be used on a single density DFS system it is recommended that each data file be kept on a

separate disc to prevent 'Can't extend' errors occurring.

OPTION 1 - DATA ENTRY

The program requires the following information for each title or record entry.

A. The tape identification number: a three digit number (between 000 and 999) which uniquely identifies the tape to the user and the database program. Pressing Return brings back the main menu.

B. The tape type: a three digit number relating to the tape length (120, 180 or 240 minutes).

C. The tape counter 'begin' and 'end' numbers: each a four digit number corresponding to the video programme start and end points. This number has a twofold purpose: it allows the user to locate a recording within a tape, and allows the program to calculate the duration of the recording and the time remaining on the tape (see notes on video recorder calibration).

D. The video programme category: a three character abbreviation such as FLM for film, SPT for sport, HUM for humour, etc. It is up to you to devise your own mnemonics.

E. The video programme title: up to eighty characters. It is advisable to keep titles short if many titles are to be stored.

OPTION 2 - EDITING

This prompts for the number of the tape to be edited. If the user presses Return at this stage, control is returned to the menu. Editing allows

the user to modify each of the information fields relating to a particular entry on a tape. Typing Return simply leaves the particular field unchanged.

OPTION 3 - SEARCHING

(to be published next month)

OPTION 4 - SORTING

(to be published next month)

OPTION 5 - LOOK THROUGH

Allows the user to browse through the contents of the database. Use the up/down cursor keys to move forward/backwards through the datafile. Function key f1 allows the user to jump to different parts of the data file after specifying a three digit record number as the target. Function key f0 returns the user to the main menu.

OPTION 6 - SAVING DATA

By specifying a filename the user can either create a new file or update an existing one.

OPTION 7 - DELETING DATA

This prompts for the number of a tape on which the delete procedure will operate (pressing Return again returns the user to the main menu). The routine then allows deletion of selected titles on a tape, or the complete removal of the tape number from the data file. Suitable safety checks to prevent accidental erasure of entries are included.

OPTION 8 - HARD COPY

(to be published next month)

OPTION 9 - PRINT LABEL

(to be published next month)

CALIBRATION OF VIDEO RECORDER

The program already caters for the three tape lengths, E-120, E-180, E-240, but you may wish to calibrate it for improved accuracy. The calibration process involves recording the tape counter number at 5 minute intervals throughout the length of each of the tape types used (this does take ages!). This information is then stored in lines 2850 to 2920. The list of data for each tape type must be terminated by 9999 as an end-of-data marker.

The calibration information for each of the three tape types enables the time remaining on each tape and the length of each programme entry to be calculated.

PROGRAM NOTES

There are some important program variables (set in PROCvars at line 2520) which need to be mentioned. M% defines the maximum number of records that are allowed. It is currently and arbitrarily set at 200. Z% holds the number of records associated with the most recently updated data file. MAXENT defines the maximum number of entries that can be made on a tape. This is arbitrarily set at 8. M120, M180 and M240 are the maximum values of the tape count for each of the three types of tape. This data is obtained from the calibration process.

It should be noted that the data entry routine is such that an exact number of characters must be entered (with the exception of the film title which uses a specially written input handler routine). This routine either accepts solely numerical data (numbers 0-9) as input or any alphanumeric character string. The type of input expected by the routine is flagged by one of the procedure call arguments. A short beep is emitted if an incorrect entry is attempted.

The options provided this month will be sufficient for you to start organising your video library. The program will be completed next month with the remainder of the routines allowing the library to be sorted, hard copy to be printed, and searches for individual titles and tapes to be made.

Continued on page 68

A SPRITE ANIMATOR

In his last Visuals column, Barry implements a Sprite Animator to put life into sprites created with last month's program.

The program developed last month allows the creation of multicolour sprites of any size. The Animator featured here will allow you to move these sprites around the screen. In fact there are four programs listed this month, so it may sound a little complicated. The main program (listing 1) is the Animator itself. This creates a block of code which includes moving routines (in machine code) together with sprite definition codes. You then create a Basic program which installs the sprite code created with the Animator, and which moves your sprites around by making calls to the sprite code. An example program is given in listing 2. But before we see how this works, we will return to listing 1.

THE ANIMATOR

To get the Animator working, first type in listing 1, and save away the program. Before you can run it you will need a datafile (made from Basic DATA statements) which it will automatically append to itself. All this data does is to tell it what mode the sprites are to be used with, and what the sprite filenames are. So to run the Animator you need a block of data similar to that in listing 3. Its structure should be clear from the REM statements. It should always start at line 5000, and should give the required mode, followed by the names of each sprite to be called. The last item is the word "END". In our example, we have included ten mode 4 sprites.

For the purposes of example, listing 4 is a short program which will actually create the ten (identical) sprite files. So if you are going to use

the Animator with the data block given in listing 3, you should first run listing 4 to create the ten sprites - phew! Now we can run the Animator. It will ask you for the name of your sprite datafile (the name under which you saved listing 3). When linking is complete, it will request a filename under which to save the compiled sprite mover code. When the job is done the program will display various data, and you should note for future use the value of HIMEM given.

```
=====
      REM Mode 4 Sprite Animator
=====
< Various totals relating to sprites >

NUMBER of sprites linked = 10
DATA table size (bytes) = 320
INFO table size (bytes) = 80
CODE mover size (bytes) = 282
OVERALL length (bytes) = 682
CODE (LOAD/EXEC) address = 45500

< Set HIMEM to 45500
=====
By B. Christie - (C) BEEBUG 1988
=====
```

SPRITES FROM BASIC

We now turn to the Basic program which will make use of the mover code. Typically this might be a game of some sort, or any program which would benefit from an animated display. As mentioned above, a sample program is provided as listing 2. It begins by assigning mode, and setting HIMEM to &5500 (the value provided by the Animator when our example sprite code was generated). This is essential as the sprite code will be held above HIMEM. Next (at line 60) is the command which loads in and installs the sprite code (use the filename which you previously supplied for saving the mover code).

The mover code provides the user with three machine code calls. The call addresses are always as follows:

```
Step Sprite &900
Move Sprite &903
Put Sprite &906
```

Put Sprite (called in line 110) places the sprite at a particular position on the screen. Before the call is made, A% should contain the number of the sprite, and X% and Y% the required co-ordinates of the sprite (see below).

Once a sprite is on the screen, it can be moved by using the other two calls. To do this you must first call Step Sprite (line 120) with A% containing the Sprite number, and X% and Y% containing the co-ordinate increment required in each re-drawing of the sprite. Then each time that you call Move Sprite (line 160) with A% containing the sprite number (X% and Y% are not required), the sprite is moved by the increment defined with Sprite Step. To remove a sprite at any time, just make a call to Put Sprite giving the present co-ordinates of the sprite to be deleted.

To keep the routines fast, the X and Y co-ordinate ranges are as follows:

Y (all modes)	range 0-255
X (modes 0, 1 & 2)	range 0-79
X (modes 4 & 5)	range 0-39

Position 0,0 corresponds to top left. Space is very tight this issue, and I must leave you to experiment with these routines. One last point, you may wish to use *FX19 before moving any sprite, to make things smoother - but it will slow everything down.

This is the last of our Barry Christie Visuals series, but we shall continue to cover visual aspects of the Beeb in future issues, and Barry will be contributing programs in future issues of BEEBUG and RISC User.

B

MASTER EMULATION ROM

In this and next month's issues, Bernard Hill evaluates two software packages which offer to turn your Model B into a Master.

Can you really turn your Model B into a Master? It's a nice idea, especially if you can retain your Model B to run all those Master incompatible games (sorry, programs). MER from Dabs Press claims to do just that.

Product	Master Emulation ROM
Supplier	Dabs Press 76 Gardner Road, Prestwich, Manchester M25 7HU. Tel. 061-773 2413
Price	£19.95 inc VAT - ROM £14.95 inc VAT - 5.25" disc £16.95 inc VAT - 3.5" disc

To attempt to turn a model B into a Master requires more than just software. Additional hardware, particularly RAM for various purposes is required as well. MER implements most of the Master's additional star commands, but its full potential will only be realised if you add some of the missing hardware facilities and this I have covered first in some detail.

The MER software is available in a variety of formats, and in all cases is accompanied by extensive documentation. Let's examine then the extent to which a Model B can be upgraded to a Master using the MER package and relevant hardware add-ons.

RAM UPGRADES TO A MASTER

If you could upgrade your Model B (or even B+) to a Master you would need quite a lot of extra memory, and this comes in various types:

1. Shadow RAM.

Firstly, you could add shadow RAM to your Model B (by Aries, Watford or Solidisk). MER works well with these; in fact it does so by behaving quite independently, leaving the star commands which drive your particular shadow RAM quite intact. There is no attempt to implement MODE 128 type statements, and even *SHADOW does not necessarily work with all shadow RAM boards.

2. Sideways RAM.

Secondly, your Model B could have banks of sideways RAM added, and that's fine too (in fact MER can handle all the known access protocols - e.g. from Solidisk, Watford, ATPL, etc.). What it can't do is handle a mixture of protocols, for instance a 16K module of Acorn User RAM sitting alongside an early Solidisk system, or with an ATPL board. But it works particularly well with sideways RAM all of one type, such as the Watford ROM/RAM board, or the Solidisk TwoMeg 128, and up to 64K can be accommodated.

3. CMOS RAM.

Thirdly, the Master has CMOS RAM, in which it keeps its *STATUS/*CONFIGURE options. MER's implementation here is excellent. If you have the Solidisk Real Time Clock installed in your Model B, then MER will use this for its 50 bytes of CMOS RAM just as the Master does. If not, then you can use the last 50 bytes of a nominated sideways RAM bank (including the one occupied by MER itself if you're running a ROM image) - preferably with battery backing. Failing this, MER will use bytes &140-&171 of the 6502 stack. If you have no battery-backed RAM then, to avoid losing all your configurations at power-down, MER has a *SCONFIG command which saves all this information to a disc file, and *LCONFIG will reload it when you switch on again. Just as on the Master, these 50 bytes hold options such as loud/quiet beep, UNPLUGGED ROMs, default modes, disc speeds, printer destinations, Caps Lock status etc. This all works splendidly and the full range of *CONFIGURE and *STATUS commands is implemented, with commands identical to those in the Master's Operating System.

4. Private RAM.

So far so good. But one final type of RAM which you can't add to your Model B is Private RAM: that's the bit of the Master which keeps PAGE down at &E00, so don't expect MER to shift PAGE down from &1900. In fact, MER needs some workspace too, and the Dabs Press made the decision NOT to use workspace (like the DFS) which would raise PAGE. Neither does MER run solely from sideways RAM and so use its own SWR image as workspace (like their other product SideWriter). To my mind that's a great pity, because MER now has to use other areas, including some of pages 6, 7 and 9 causing workspace clashes with other ROMs (such as BEEBUG's own Master ROM).

FACILITIES

So you've got your Master Emulation ROM installed. Just what have you got you didn't have before? Briefly put, you have the commands which are available on the Master and the Compact. For the first time you can use *APPEND to supplement *BUILD; *SPOOLON to supplement *SPOOL; *EX to add to *INFO (even on DFS, tape and ROM filing systems!); *CREATE to add to *SAVE; *FREE and *MAP to add to *CAT on the DFS and *REMOVE to go with *DELETE. You could fit a 1770 interface to run the ADFS and yet keep the ADFS *UNPLUGged to conserve PAGE. You can allocate sideways RAM as DATA with *SRDATA or *SRROM, and even call !D if you have View 3. If you have no Real Time Clock fitted then *TIME gives one second before the year 2000, like the Compact.

In fact the whole system FEELS just like a Master, right down to the "Acorn MOS" prompt on Break (the "BBC Computer 32K" has gone). Your Beeb even enters a 'No language' environment if you *CONFIGURE LANG to a socket which isn't a language, and the only difference from a real Master which I have spotted is, as mentioned above, that shadow RAM support is left to your shadow support ROM. And in order to 'disable' your Master there's a *MODELB command which completely kills MER and leaves you with your old system until powered-up again. The kids can still run Elite!

TEMPORARY FILING SYSTEMS

But the most impressive implementation is an almost-complete emulation of the Master's temporary filing system commands. This may be nothing new to Master users, but to be able to *-TAPE-CAT, *-ROM-EX or even *-ADFS-CDIR without interrupting your DFS working is quite an eye-opener to me! And *MOVE too? Many times I have wanted to make a second copy of a data file on the same disc but under a new name, and have to resort to *LOAD and re-*SAVE, but now I've got *MOVE <file1> <file2>. And if you have got an ADFS, from ADFS to DFS too - and vice versa - what a joy (even if it does take an age).

But I dare say you noticed the description "almost complete". What's missing? Nothing really, but we do come bang up against that workspace problem. Perhaps because MER uses

page 9, I've not managed to successfully *MOVE between tape (or RFS) and disc. Sometimes the file is corrupt when MOVED, and sometimes it just crashes. LOAD "-TAPE-name" and reSAVE is fine, however. And perhaps the most serious drawback I've spotted is that I can't SAVE and LOAD from View 2.1 (page 7 being used for workspace is naughty as it really is the property of the current language) although READ and WRITE are fine. And anyway View 3 doesn't show this problem. David Atherton at Dabs Press tells me that they are looking into these problems.

COMPATIBILITY

The launch of a product like MER (at such a reasonable price) takes considerable courage for Dabs Press. Not only do they have to try to match all of the third party hardware add-ons but they also have to aim for compatibility with Master software. Here the issues are perhaps clearer to see, or at least it is easy to predict what won't work. First, the Master has a 65C12 processor with extra instructions which the 6502 hasn't, and you can't run machine-code software which uses those. Secondly, there is software which needs the extra space, which the Master's page value of &E00 gives (or machine code which loads into this area) - that's out too. And then the Master software may need some of the workspace which MER uses (such as View 2.1, and the BEEBUG Master ROM). Finally, there are some aspects of the Master OS which can't be emulated, such as the new OS calls, e.g. OSWRSC at &FFB3 (Bang goes my Colossus 4 64K version), or ROM polling. For this reason you can't expect MER to run all Master software, but Dabs Press claim that their ROM is compatible with 90-95% of what's available.

One final point. If you buy MER, be sure you have a copy of version 2.01 (it's the one with an addenda sheet for the manual). If you have version 1.0, then Dabs will exchange it free of charge, and David Atherton also assures me that he operates a money-back guarantee if you have tried to work MER with some strange alien hardware and failed. That has to be a very fair offer.

Next month Bernard Hill takes a look at the Solidisk Real Time Clock mentioned in this review and provides some final thoughts on both products.

B

text\$ to the right of character five being assigned to the variable B\$. A neater solution is to use a shortened version of MID\$:

```
B$=MID$(text$, 6)
```

When only one numeric parameter is given with MID\$, then all the characters from that position onwards are extracted (in the example, 6 is the starting position, one more than 5). In practice, most string manipulation uses this shortened form of the MID\$ function, and the LEFT\$ function.

PLAYING WITH STRING

Now we know enough to begin to write some useful routines. One of the most frequent requirements is to extract each character of a string in turn. This can be achieved with a simple FOR-NEXT loop, as in this short example:

```
100 INPUT word$
110 FOR I=1 TO LEN(word$)
120 letter$=MID$(word$, I, 1)
130 PRINT letter$
140 NEXT I
```

Line 100 waits for any character string to be typed in, and the loop will then list each letter in turn down the screen. Try it and see. Here's another example. See if you can work out what this will do before trying it in on your machine:

```
100 INPUT word$
110 FOR I=1 TO LEN(word$)
120 PRINT LEFT$(word$, I)
130 NEXT I
```

Replace line 120 with:

```
120 PRINT MID$(word$, I)
```

In fact the result will look even better if you change line 120 to:

```
120 PRINT SPC(I-1);MID$(word$, I)
```

These may seem trivial examples, but the facility to extract and manipulate strings as we have in these examples is the foundation for more extensive usage. As a test of your own ability, try to write a modification of line 120 above which will print any word with each letter in turn replaced by a space (see illustration) - answer at the end of this article.

SEARCHING EXAMINATION

One common requirement is to be able to search a string for the presence of one or more characters. This is what the INSTR function is designed to do. For example, we might write:

```
REPEAT
INPUT"Answer Y or N" ans$
OK=INSTR("YyNn", ans$)
```

UNTIL OK>0

Many programs have instances where a yes/no answer is required to some question, and there are various ways of handling this. In the above example, the response to the question is assigned to ans\$ (assumed to be a single character). The INSTR function then searches the first string specified (the string "YyNn") to see if it can match the string ans\$. If a match is found then the position of the matching

character is assigned to the variable OK. If no match is found then zero is assigned. Putting our two statements inside a REPEAT-UNTIL loop as above will mean that the question is repeatedly asked until one of the desired letters (YyNn) is input.

Be careful, though, in using the result of the INSTR function in a logical way. If you are ever tempted to use the combination:

```
NOT INSTR(. . . .
```

then you are likely to get misleading results (see Beginners Start Here Vol.4 No.2).

Another common occurrence is when we need to check a string for a particular character, for example:

```
INPUT"Which option?" option$
ch=INSTR(option$, "/")
IF ch THEN mod$=MID$(option$, ch+1):
option$=LEFT$(option$, ch-1)
```

Here, we input an option which may or may not have '/' followed by further characters appended at the end. The INSTR function searches for this character, and if found the characters following the '/' are assigned to mod\$, and option\$ is assigned that part of the input string to the left of the '/'. Note how the '/' character itself is dropped altogether.

There are two further examples which are well worth looking at. Suppose we want to find all the occurrences of a particular character in a string. Here is an example:

```
100 INPUT"Enter any character" char$
110 INPUT"Enter any string" string$
120 pos=0
130 REPEAT
140 pos=INSTR(string$, char$, pos+1)
150 IF pos>0 THEN PRINT pos
160 UNTIL pos=0
```

This uses a variation on the INSTR function in which a third numeric parameter is included. This determines the position within the search string at which the search will commence. To

```
ASINGSTOKE
B SINGSTOKE
BA INGSTOKE
BAS NGSTOKE
BASI GSTOKE
BASIN STOKE
BASING TOKE
BASINGS OKE
BASINGST KE
BASINGSTO E
BASINGSTOK
```

start with **pos** is set to zero so that the search starts at the first character (position **pos+1**). If the character being searched for is found, then **pos** will be assigned the position in which it occurs, and the next search commences at the character following that occurrence, hence the **pos+1** (hence the reason why **pos** has to be set to zero initially, not one). The REPEAT-UNTIL loop terminates when no more occurrences of the specified character are found.

We can use this idea as the basis for a second type of search, one where we want to find all the occurrences of more than one (single) character. Amend the last example with the following lines:

```
100 flag$=".,;:!?"  
105 FOR I=1 TO LEN(flag$)  
106 char$=MID$(flag$,I,1)  
.....  
170 NEXT I
```

Now, any string input will be searched for all the occurrences of each of the characters in **flag\$**.

VERSATILE INPUT FUNCTION

To conclude this month's article, I want to give you a more substantial example of character manipulation in action. In this case it is an input function. It is often desirable to implement one's own input function rather than use the standard INPUT of Basic. It gives us much greater control over what is happening, allowing the characters input to be checked in any way we wish. In this case, the function, called **FNinput**, allows a prompt to be specified as well as a position on the screen (**x,y**), the maximum number of characters to be input (**width%**), and a so-called 'paint' character which is used to paint or mark the data entry field on the screen. I suggest you type in the listing and try it out before proceeding any further.

The variable **char\$** holds each character as it is typed in, and the variable **pos** records the current entry position within the data entry field. The variable **string\$**, initially set to a null entry, holds the current form of the complete input string. Three possibilities are catered for: if Delete is pressed (ASCII code 127) the last character is deleted both from the screen and from the variable **string\$**. If the entry field is full, a 'bleep' is sounded. Otherwise the character is displayed and appended to the variable **string\$**. When Return is pressed the

function returns the contents of **string\$**. Line 110 shows a simple call of this function.

For clarity, the coding for the append and delete functions has been put in a separate procedure in each case. Note too, the use of two further string functions. **ASC** returns the ASCII code of a character and is useful for dealing with non-printing characters like Return. **STRING\$** is a simple way of replicating a sequence of characters.

Try calling the function with different parameters. See also if you can modify the function to accept upper case letters only, or digits and decimal point only. More on characters next time.

```
10 REM Program InputFN  
20 REM Author Mike Williams  
100 MODE 3  
110 Z=FNinput(10,10,"Test Input",10, ".")  
120 END  
130 :  
1000 DEF FNinput(x,y,prompt$,width%,paint$)  
1010 LOCAL string$,pos:string$="":pos=1  
1020 PRINTTAB(x,y)prompt$;": ";STRING$(width%,paint$)  
1030 PRINTTAB(x+LEN(prompt$)+2,y);  
1040 REPEAT  
1050 char$=GET$  
1060 IF ASC(char$)=127 AND pos>1 THEN PROCdelete ELSE IF pos>width% THEN VDU7 ELSE IF ASC(char$)>=32 AND ASC(char$)<127 THEN PROCappend

```

(B)

ACORN IN ACTION

A totally new experience for show visitors

at the
Royal Horticultural Hall,
Westminster, London SW1

10am-6pm Friday May 13
10am-6pm Saturday May 14
10am-4pm Sunday May 15

You'll find the very latest software and peripherals for the complete Acorn range at the Electron & BBC Micro User Show.

But this time there'll be so much more to enjoy.

Acorn In Action will demonstrate some of the truly amazing projects currently involving the machines...

SEE

- ★ A spectacular laser light show controlled by a BBC Micro. (Saturday only)
- ★ The research work on the BBC Micro that has helped to bring new hope to sufferers of the eye disease glaucoma. (Friday and Sunday)
- ★ A program developed by an amateur astronomer to locate distant galaxies. (Saturday and Sunday)

- ★ The Beeb system being used by doctors at Guy's Hospital to provide a breakthrough in the treatment of arterial disease. (Saturday and Sunday)

PLUS

watch your own heartbeats displayed, measure your manual dexterity and hear your own voice backwards – all courtesy of a BBC Micro.

Take your seat in the Archimedes Demonstration Theatre run by Acorn's own experts. Thirty minute special introductory courses to the new machine will be held on the hour, every hour throughout the three days. Price just £1.

It all adds up to a fantastic day out for the whole family!

Avoid the queues! Get your ticket in advance – and SAVE £1 A HEAD!

Post to: Electron & BBC Micro User Show Tickets,
Europa House, Adlington Park, Adlington,
Macclesfield SK10 4NP.

Royal Horticultural Hall
Westminster
London SW1
May 13-15, 1988

Advance ticket orders must
be received by Wednesday,
May 4, 1988.

Nostalgia

Remember "Countdown to Doom"? Peter Kilworth's classic sci-fi adventure may well have been the first game you ever fought. Well, RETURN TO DOOM - Part 2 of his Doom trilogy - is now available from Topologika:

You are flying through the universe, minding your own business, when a distress call comes in. "Mayday! The Galapoxi, taking the Ambassador of Regina on an important mission to Flaxo, has just crashed on Doom. Rescue needed! Heading for Glett..." As the only person ever to have survived Doom, you steer once more for that dangerous planet. This could be your finest hour.

Or maybe even longer....

As tough as Countdown - but a different sort of challenge - RETURN TO DOOM is sure to bring back memories. £12.95 inc disc, manual, VAT and P&P.

THE MASTER PAGES

Devoted to the Master
Series Computers

In our Master pages this month, Lee Calcraft shows how the ADFS routines presented in the previous issue may be combined into two complete utility programs. One is a customised ADFS menu system, the other a useful 'CATALL' facility.

Dave Somers has been looking at the Master Extensions ROM from DABS Press, and we complete this section with further hints and tips specific to the Master and Compact.

**MASTER
SERIES**
TALKING TO
THE ADFS
(part 2)

Lee Calcraft concludes his experiments on the ADFS with the implementation of two utilities: a customised ADFS menu and a whole-disc catalogue.

Last month we explored the use of certain filing system calls to create three packaged procedures which could be used to read catalogue and other allied information from an ADFS disc. Here we will put those procedures to work in the implementation of two utilities. Both require lines 1000 onwards of last month's code, though none

of the lines before 1000 are needed. I suggest therefore that you load in last month's program, if you have it, and delete the lines lower than 1000, and save the remainder away for future use.

CUSTOMISED ADFS MENU

With lines 1000 onwards in your machine, type in this month's listing 1. This will implement a complete ADFS menu. When the program is run you will see something similar to that in the accompanying figure. Near the top of the screen are displayed the current drive number, and directory name and title (all obtained by calling PROCtitle). Then below that in alphabetical order is a display of objects in the current directory. Each has a letter beside it, and all directories are marked in reversed out text. Pressing a letter corresponding to a directory name causes that directory to be selected, and the menu to be re-displayed. If you press a key corresponding to a Basic program, it will be chained in. At present there are no options for loading text files into word processors, but this feature is easily added (see later).

Customised Menu Keys

^	Go to root directory
<	Go to the previous directory
v	Go up one directory
0	Select drive 0
1	Select drive 1
*	Perform star command
Ctrl @	Quit

Other options currently implemented include star commands, and the use of cursor keys to take you to the root directory or to move up one directory, or to the last selected directory.

To change drives, or change a disc, select the required drive with the "1" or "0" keys. Finally, Ctrl-@ may be used to quit the menu.

PROGRAM NOTES

The menu is controlled from the short REPEAT loop in lines 130 to 170, which calls 3 procedures. PROCtoppart handles the top few lines of the menu, including the title, drive and current directory information. This is obtained by calling PROCtitle. PROCtoppart also calls PROCfile, the second of last month's procedures, reading in the names of the objects in the current

directory and their total number, *fileno*. If this variable is greater than zero, then the main program loop at line 150 calls PROCreadcat. This in its turn calls the third of last month's procedures, PROCcatinfo, to obtain data on object type (whether each object is a file or directory), plus load and execution addresses etc. PROCreadcat is responsible for displaying each object name in the menu in an orderly fashion.

Finally the main loop at line 160 calls PROCchoice to wait for a key press. Key presses which involve file or directory selection are handled in the procedure PROCfiledir. This currently has two possible outcomes, if the selected object is a directory, then that directory is selected. Alternatively if the object is a file whose second byte of its execution address is &80, then it is assumed that the object is a Basic program, and it is chained. It is an easy matter to implement further actions here. For example, you might check that the load address of the file is &8000 using:

```
IF (file%(key-64,1) AND &FFFF)=&8000
and load it into sideways RAM, or that its
execution address is &FFFF using
```

```
IF (file%(key-64,2) AND &FFFF)=&FFFF
and load it into Wordwise.
```

A *CATALL FACILITY

By calling the second and third procedures in a recursive manner, we can implement a number of useful utilities. The one covered here will catalogue the whole of an ADFS disc, displaying all directories, with nested files down to the full depth of 127 levels of nesting permitted on the ADFS. As the program currently stands, directories are displayed in

reversed out text, and each new level of nesting causes the display to be indented by four character positions. If you have a disc which nests below about 15 levels, the display will wrap around, but if this is a problem, you can change the indenting factor (the second 4 in line 410 could be reduced to 2, 1 or even 0).

The program centres around the procedure PROCdispall, called in line 140. This is used recursively as follows. It begins by calling PROCfile and, indirectly, PROCcatinfo (the second and third procedures from last month), and displays the results as a list of objects in the current directory. When it encounters a directory name, it stores its current position in the array *ends%(level)*, executes a *DIR to the directory name encountered. It then calls itself (i.e. PROCdispall calls PROCdispall), and begins to display the contents of the new directory, until it encounters another directory name. This process will repeat each time that a nested directory is encountered.

As it continues its display of objects, it will eventually reach the end of the current directory (i.e. the directory which it is currently displaying). When this occurs, the procedure executes *DIR ^ to move up one level, and then terminates (i.e. with ENDPROC), thus dropping the program back into the procedure which called it (i.e. PROCdispall at one level above). The display then continues from where it left off until it reaches a new directory, in which case it makes another recursive call, or it reaches the end of the current directory, where it goes back one level. Eventually, the program "surfaces", and the display is complete.

Even if the program is a little difficult to describe, it works very effectively, and can be most useful in finding lost files and so on. It is also relatively easy to modify to suit other requirements. For example, it is very easy to make it print only the names of directories, should that prove useful. Also without much trouble it could be used to find a given filename on a disc. To do this, simply suppress the display, and insert a line which checks the current object name (file\$(A) in line 430) against the required filename. The possibilities are endless, but if you do come up with some snappy applications of the main routines listed last month, please drop me a line.

Continued on page 46

Dave Somers takes a look at MOS Plus from DABS Press - a utility ROM to enhance (and correct) the Master's Operating System.

Although the Operating System (OS) on the Master microcomputer is excellent, it does have a number of irritating bugs and omissions.

This is where MOS+ from DABS Press comes in, for it fixes these bugs in OS version 3.10, and adds some very useful additional commands.

Product Supplier	MOS Plus DABS Press 76 Gardner Road, Prestwich, Manchester M25 7HU. Tel. 061-773-2413.
Price	£12.95 inc VAT (ROM) £7.95 inc VAT (5.25" disc) £9.95 inc VAT (3.5" disc)

It comes in the form of a sideways ROM, and can be supplied either as a ROM, or on disc for loading into sideways RAM. An eleven page A5 instruction manual details its various facilities. After installing MOS+, the sign-on message produced by the computer changes from "Acorn MOS" to "Acorn MOS+" to let you know that everything is OK.

ENHANCED STAR COMMANDS

A number of enhancements have been made to some of the star commands, with quite a few of them as found on the Master Compact. Both *APPEND and *BUILD will now accept all 256 ASCII characters, rather than the first 128 as before. When loading data into sideways RAM, using either SRLOAD or SRWRITE, an optional "T" parameter can be added to initialise the data. For SRLOAD, this removes the need to press Ctrl-Break before an image is recognised by the Operating System. *UNPLUG can also have this parameter added, in which case the ROM is unplugged immediately, by removing its entry from the ROM information table.

*SHOW has been tidied up so that omitting a key number will cause all the key definitions to be displayed. For *STATUS, the entries are now displayed in alphabetical order, and *ROMS lists Sideways RAM as "RAM", and doesn't duplicate entries.

To backup discs, you don't have to search for the Welcome Disc, as MOS Plus comes complete with the necessary code. *BACKUP automatically handles both DFS or ADFS formats, and if required can use sideways RAM to speed up the process. You can also use it to backup (on DFS discs) from side :0 to :2 (or :1 to :3) on separate discs - it automatically prompts you to change discs.

The *BASIC @ command has been extended so that the tokeniser will accept text from any location, and not just from the EDIT's buffer.

NEW STAR COMMANDS

Nine new star commands have been added. For ADFS users, *DRIVE has been added to allow DFS software using this command to still work under the ADFS; *CATALL will catalogue all the files on the disc; *EXALL is similar to *CATALL, but performs *EX on all files; *FIND will search for a specified file (with wild cards allowed) and display their path if found. A formatter and verifier are also included.

A command called *SETTIME can be used to set the date or time or both of them. The syntax is identical to Basic's TIME\$ command. This will allow the RTC to be modified within other languages that do not support it, eg Comal. To complement the sideways RAM handling commands, *SRKILL will clear out the first 16 bytes of one or more RAM banks.

ALARM CLOCK SYSTEM

Part of the 146818 Real Time Clock contains an Alarm Clock facility, which is unfortunately not implemented by the Operating System. MOS Plus allows you to use this, provided you make a link on the main circuit board.

*ALARM is used to control the system. If followed by no parameters, the current setting will be displayed. The alarm can be configured

to go off every second, minute, hour, or at a specific time. When the alarm is triggered, a beeping noise is made. Its volume can be adjusted to either low or high, and can be set permanently in the CMOS RAM, if required. For machine code users, the alarm can be trapped by intercepting user event number 9.

MOUSE DRIVER

To avoid having to install a ROM such as AMX, etc., MOS Plus comes with the mouse driving code necessary, along with the OSWORD &64 call to access it.

BUG FIXES

With OS 3.10 there were a couple of bugs which could occasionally cause problems. The infamous CLOSE#0 bug, where the DFS does not close files with the correct length in the event of *CLOSE or CLOSE#0, has now been fixed; after *EDIT there can be any number of

spaces before the filename; if more than one filename is specified after *REMOVE, the call will correctly fail.

When re-setting the CMOS RAM with R/power-on-reset, the settings now default to sensible values.

HELP SYSTEM

A series of help texts can be obtained about MOS Plus itself, the Alarm facility, Basic, View, and Terminal. This is an excellent aide-memoire.

FINAL THOUGHTS

MOS Plus is an excellent product. It offers all those facilities which you are likely to use without having to resort to the Welcome Disc, and a few others that are most useful. It has been well thought out and is a most welcome addition inside any Master. B

SIMPLE AUTO-SAVE

Lee Calcraft

The following EXEC file will automatically save a Basic program under the name stored in a REM line within the program itself. The format is similar to that used on the Archimedes and in the Master ROM. The EXEC file should be created using a word processor or the Master's text editor, and could be saved under the name "S". Once it is installed in your Library directory, every time you issue the command *S your currently resident Basic program will be saved with the name given. The format for the filename is:

```
10 REM >filename
```

The name must immediately follow the ">" character, and must itself be at the end of a

*| Automatic Program Save

```

SS=$ (P%+1)
VDU6:P.TAB(3)"SAVING ";SS
SAVE SS
```

program line. The only other proviso is that the ">" character must fall within the first 100 bytes of the program.

The routine displays the name of the file which it is using for the save, or if it finds no name, it will beep and report the fact.

AUTOMATIC BACKUP (ADFS)

Lee Calcraft

Whether you are using the Master ROM to implement an auto-save facility, or the method described above, you can create an additional command to back up any program to a separate drive by altering just one line of the above. Simply replace the third line from the bottom (SS=\$ (P%+1)) with the following:

```
SS="$":1$.ProgBackup."+$ (P%+1)
```

Now re-save the entire EXEC file under the name PB (for Program Backup), and every time that you type *PB the Basic program currently in memory will be saved to the directory **ProgBackup** on drive 1, using the so-called "incore" filename with the same format as above. Again the routine will report on its progress, and will inform the user if no suitable filename is found. B

PRINTER ROMS

If you feel that you are not getting the most out of your printer, or you can't cope with the multitude of printer codes, you might find one of the two ROMs reviewed by Geoff Bains quite useful.

The skill required to master the Escape codes used to get the most out of your dot-matrix printer is quite rightly held by many people to be on a par with quantum theory. These two ROMs go some way towards making life with your printer easier.

Product	PrintROM
Supplier	Windmill Software Smock House, Hull Lane, Terling, Chelmsford, Essex CM3 2QD. Tel. (024533) 371
Price	£15.95 (ROM) £10.95 (SWR)

PrintROM is available in ROM or on disc ready for sideways RAM, and in ten different versions for different printers. Most of the printers beloved by Beeb owners are catered for - Taxan KP810, Epson LX/RX/FX/MX, Canon PW1080, Centronics GLP, Brother M1009, Panasonic KXP1080/1, Shinwa CP-80, Juki 5500, MP165 and Star SG-10. However, the newer 24-pin machines are particularly noticeable by their absence from this list.

PrintROM is essentially a memory aid. With a series of star commands of obvious and memorable names, the most commonly used (and forgotten) printer code sequences can be easily sent to your printer. Like all star commands, these can be issued either in immediate mode, from within Basic programs or from Wordwise Plus, Interword and some other word processing software - either from the menu or embedded in the text.

The common printing effects are covered. Some commands are followed with ON or OFF to select the effect, and others require numbers. The *CHARSET command used to select the international character set presents the user with a mode 7 menu of the nine possibilities selectable with the cursor keys.

The *CMENU command presents a menu of all the other commands - handy for leaving any decision about a document's presentation until the last minute. However, this menu is somewhat ruined by not accepting lower case letters to select the effects. To have to switch to upper case (mentally or on the keyboard) in a menu which supposedly saves keypresses is just silly. In addition, a very useful *LPRINT command is provided, which prints the characters following it, and a graphics screen dump is provided for good measure (the Taxan dump is a good one but printer dumps are two a penny these days).

If you are totally baffled by your printer then PrintROM will help. It has the great advantage of being model-specific and so requires no setting up, and for the most part is pretty self-explanatory. However, a hefty £16 for what amounts to simple code substitution is not good value. For my part, I would prefer to invest a few pence in a list of codes to stick on the wall above the monitor.

Product	Hyperdriver
Supplier	DABS Press 76 Gardner Road, Prestwich, Manchester M25 7HU. Tel. 061-773 2413
Price	£29.95 inc VAT (ROM) £24.95 inc VAT (SWR)

Hyperdriver is an altogether different story. This is a cleverly thought out package that doesn't just substitute for your own mastery of your printer but augments it. It is of course much harder in itself to master but is ultimately worth the time taken. Hyperdriver is for Epson compatible printers. However, as the vast majority of printers around today are (at least) Epson compatible this shouldn't pose too many problems.

Like PrintROM, Hyperdriver is based on star commands which substitute for the hard-to-remember printer Escape codes. Many more printing effects are also controllable. There is little your printer can do which isn't covered by this ROM. The Hyperdriver commands are all two letter mnemonics. Although this makes the commands convenient to type, it doesn't help their memorability. True, they all follow a logical pattern - *UL for underline, *XU to cancel underline. *IT for italics, *XI to cancel italics - but the pattern is the author's and not

your own. I would have preferred to see full commands which could be abbreviated. However, this is a minor gripe. This command set, like all others, is soon learnt.

Hyperdriver does not just stop at code substitution. For a start, the software is much more 'intelligent' than PrintROM.

If something is dangerous or impossible it says so. The error messages are always clear and appropriate. This ROM has the unusual habit of requiring acknowledgement of all error checks. After each error message you must press Return to continue. This does have the advantage that you cannot miss the error. However, it just gets tedious after a while. It would be nice to be able to switch this feature off!

A more useful feature is that Hyperdriver commands can be strung together into 'macros'. This both saves on memory space and is very convenient. The macros can be saved to disc and loaded back in with simple commands. By using different sets of macro definitions, a single document, liberally embedded with macro calls, can easily be printed in any number of different ways just by loading up the required macro definitions first.

All this is fine for users of Wordwise Plus or Interword, but View and View Professional users cannot embed commands in their documents. For them, Hyperdriver includes a complete View printer driver. The commands are embedded between the View highlights, and the driver interprets them to give the correct control codes to the printer when the document is printed. Of course that removes the WYSIWYG nature of View. Wordwise Plus is not a WYSIWYG word processor to start with.

But Hyperdriver can even fix this for you. First the Beeb is switched to 'test print' mode. Now all attempts to print are redirected to the screen without the usual reams of wasted paper trying

to get the layout right. Now switch on the 'screen effects' and the common printer effects such as enlarged text, italics, underlined, bold, superscript and subscript can all be produced

As well as making easier many standard printer effects such as italics, enlarged, condensed, emphasised, and sub or superscript, Hyperdriver can also produce text in a pseudo near letter quality style of print on standard non-NLQ printers and screen-style print in the same range of sizes as you will find on the Beeb

on the screen - true WYSIWYG. Of course none of this is as convenient as using a word processor which provides true WYSIWYG in the first place but for View or Wordwise Plus users it's a boon.

Not only can Hyperdriver simulate the

printer on the screen, but it can also print screen characters (including user defined ones) on the printer. 'Graphics print' produces a sort of continuous text printer dump of characters on paper. All the same printing effects are there but in a new font and at different sizes depending on the screen mode you are in. It's a nice touch and can be quite useful.

What is certainly useful for owners of older printers is the NLQ mode. This produces NLQ print on printers without an NLQ facility with three passes of the printhead over the paper. The result is not as fine nor as fast as some NLQ printers' output and is only available proportionally spaced. Nevertheless, it is a useful addition and quite adequate for most needs.

In many ways Hyperdriver and PrintROM are just two of kind with the higher price of Hyperdriver just serving as a deterrent. However, looking beneath the surface and considering the way the ROMs treat errors, the thought that's gone into the way Hyperdriver is used with word processors and a million other good design features of Hyperdriver, the far greater value of this ROM stands out.

Many Beeb users can live in peace with their printer without assistance from anyone. However, if you are one of those who feel there is more to a printer than wading through lists of Escape codes, Hyperdriver will prove an ingenious blessing. B

*FILTER

*Filter Circuit

R1,1,2,50

R2,3,E,50

C1,2,E,625p

C2,3,E,625p

C3,2,3,32.15p

*a lossy inductor

*0.74 microhenries

*with a Q factor of 20

L1,2,3,0.74u,20

FMIN=10M, FMAX=100M, LOG, STEPS=10

IN=1

Figure 3. Filter Circuit File

Firstly, comments have been introduced. They must start on a new line, and be preceded by an asterisk. The analysis program completely ignores all comments. Secondly, figure 3 contains a lossy inductor; that is to say an inductor which has a non-inductive element to its impedance (like all real inductors). This is represented by the string:

L1,2,3,0.74u,20

In other words, inductor L1 lies between nodes 2 and 3. It has an inductance of 0.74 micro Henries, and a Q factor of 20 (the "Q" factor of a coil gives a measure of its quality - how near to an ideal inductor it actually is).

*WIEN

*Wien bridge

R1,1,2,1000

C1,2,3,1000p

R2,3,E,1000

C2,3,E,1000p

FMIN=100K, FMAX=200K, DF=10K

IN=1

Figure 4. Wien Bridge Circuit File

The only other new element also appears in the filter file. Here the frequency range for analysis is given as:

FMIN=10M, FMAX=100M, LOG, STEPS=10

This requests an analysis in the range 100-200 MHz. But instead of the linear sweep of last month's example and of the Wien bridge, a logarithmic sweep is requested. The "STEPS=10" means that 10 steps are required in the given range. While on the subject of frequency sweeps, if you require analysis at a single frequency only, then you should replace the frequency definition line with one such as the following:

F=10M

which will cause analysis to take place at 10 MHz only.

HOW THE PROGRAMS WORK

The analysis program simulates forcing a current of one ampere into the input terminal and out of the common terminal of the circuit to be analysed. It calculates the voltages at all the nodes by solving N simultaneous equations in N variables, where N is the number of nodes. The variables of the equations are in general complex (unless the circuit contains neither inductors nor capacitors), so the voltages are also in general complex. At the end of the analysis program the real and imaginary parts of all node voltages are stored to disc, together with information about the number of frequencies, type of frequency sweep and circuit file name.

The display program reads data from the disc, and calculates the ratio of the voltage at the selected node to the voltage at the input node. This gives the voltage gain between the input and the selected node. If the selected node is the input node, the input node voltage is displayed as the input impedance.

The program may give errors if there is a very large ratio between the values of components used - the capacitors in a quartz crystal's equivalent circuit, for example. The program can handle relatively complex circuits with the following constraints. The number of each type of element used is limited to 30 (25 in the magazine disc version) by the size of the arrays (and by your patience during analysis). The number of frequency steps is limited to 80.

Some error trapping is provided: if you try to read a non-existent file, you'll be invited to try again. If you miss a connection between two nodes, you get a division by zero error, and can re-enter Wordwise to correct the circuit file. This also happens with 'No such variable' errors, which mean that information is missing from the circuit file. The program also checks the lines it reads from the circuit file to make sure it understands them and that they have the correct number of parameters.

PROGRAM NOTES

The analysis program will happily read files written using VIEW as well as those written with Wordwise, but the VIEW user must provide different methods of re-entering the editor.

The program normally reads disc files but if you have a RAMdisc (e.g. Opus Challenger), it will speed operation of the program.

ADFS users should alter line 3210 to read:

```
*CAT 0
```

If you write a !BOOT file:

```
*BASIC
```

```
CH."ANALYSE" (adjust name as reqd)
```

and type *OPT 4,3 then you can just press Shift-Break to start the analysis process, even from within Wordwise.

the extended analysis program (capable of analysing circuits containing transistors, OP amplifiers, FETs, transformers etc.), modified as described here, together with this month's display program. A number of circuit descriptor files are also included. Additionally there is a text file describing how to use the extended features.

If readers would like a listing of the extended

features of the extended analysis program (including details of the code, they should send an A3-DAT to the publisher

address, with the envelope marked
"Circuit Analysis".

EXPLORING ASSEMBLER

Part 8

A series for complete beginners
to machine code by Lee Calcraft

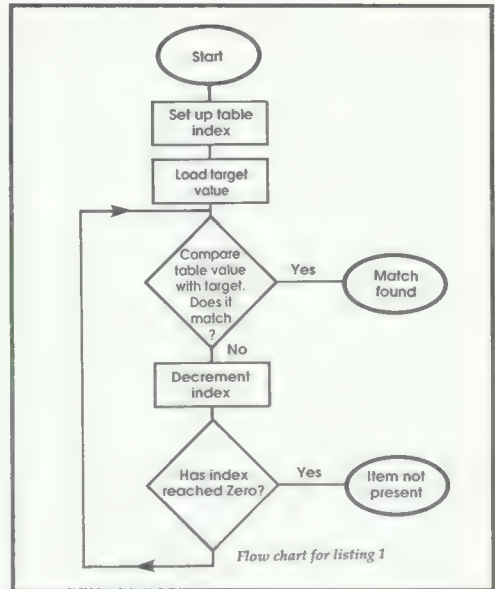

This month: Searching and look-up tables

A SIMPLE BYTE-SEARCH ROUTINE

This month we continue our discussion of the use of the CMP instruction with a look at the problem of searching. We begin with a very simple byte-search routine. Its function is to check a list of up to 255 elements to see if a particular byte is present. We will assume that the list is held at &A00 onwards, and that its elements are in no particular order. Essentially the search routine will need to compare the target value with each of the elements in turn until either a match is found, or until the list is exhausted.

The program in listing 1 achieves this. If you type it in and run it, you will be asked for a target value to be searched, and you should supply any integer between 0 and 255. The machine code search routine will then be called, and the result displayed. For the purposes of the example, the table of values examined by the program is created with a short Basic routine at line 300. This places a set of data of value between 0 and 127 in the table. Thus if you search for any integer in this range you should get a match, and not otherwise.

As we look through the listing, you may find it useful to check through the accompanying flow chart. The main routine begins at line 130 where the Y register is loaded with the number of items in the table, and the accumulator is loaded with the target value input by the user. In line 160 the target value is compared with the first value in the table (CMP table-1,Y). We have used indexed addressing for the CMP instruction so as to be able to point to each element in the table in turn. You will also notice that we have used *table-1* as the base address rather than *table*. This is because we are decrementing the Y register after each failed comparison, and checking that we have not

reached the end of the list by testing Y for zero (line 220). Thus the last value of Y for which a comparison test is made is 1. By using a base address of *table-1* we ensure that the final element of the table at address *table* is checked.

There are two exit conditions: if the number of items in the table is exhausted, or if a match is found. In the former case we return with zero in the accumulator (line 210), in the latter the accumulator is loaded with &FF (line 240). The Basic program has then to check the contents of the accumulator on exit in order to display the result of the search. This is accomplished in line 380:

```
Z=USR(&900) AND &FF
```

The USR function is an alternative way of calling a machine code routine (briefly introduced in part 5 of the series), and unlike the CALL statement, it returns a value. This value is a four-byte word made up of the contents of the accumulator, X and Y registers and status register at the time of exit. To obtain the contents of the accumulator (the lowest byte of the value returned by USR), we AND this four-byte word with &FF. The result is then displayed in line 390.

STRING SEARCH

The second program implements a string search. Here the user supplies a target string

Listing 1

INT"Item not present":VDU7
400 UNTIL FALSE
```

which is matched against a list of words. Again the program indicates whether a match was or was not found by loading the accumulator with &FF or 0 respectively. Because we are matching complete words, rather than single bytes, the routine is a little more complex than the search discussed above. But the approach is essentially similar in that it uses the LDA and CMP instructions to repeatedly compare single bytes.

In the present search program we will assume that the table of words uses the carriage return character (&0D) as an end of word marker, and that the end of the table is indicated by a byte of

value zero, immediately following the carriage return associated with the last word in the table. Lines 440 to 500 of the program are used to set up the table. For our example, I have used an alphabetical sequence, although this particular search makes no assumption about the order of the words supplied.

If you run the program, you may enter any word at the prompt, and you will be informed whether it is present in the list or not. As you will observe, the search is not case sensitive. This is achieved by operating on the user input characters with AND #&DF. This is achieved in line 200 of the program, and forces each character of the user-supplied string into upper case. The technique assumes that only alphabetic characters will be input. You can see how it works if you type the following three lines:

```
PRINT ASC("A")
PRINT ASC("a")
PRINT ASC("a") AND &DF
```

You will see that the first and last results are the same.

```

HOW THE PROGRAM WORKS

As with the last program, the table of data is held from &A00 onwards, and we have again restricted the size of the table to a maximum of 255 characters. This keeps the coding a little simpler than it would otherwise be. Again we have used Y as an index to the table, and this time we also need an index to the current test character in the target word, since we must test for the presence of the target word a single character at a time.

The program begins by loading the two index registers X and Y with &FF. We have not loaded them with 0, as one might have expected, because it is convenient to have the INX and INY instructions which move to the next character, at the start of the main loop.

Thus by loading them with &FF and incrementing them by one, we ensure that both start with the value zero. Line 190 then loads in the first character of the target string, which is forced into upper case. The result is immediately compared to the first character in the table. If the two match, a test is carried out on one of the two matching characters to see if it is a word terminator (CMP #13 in line 230). If so, it means that two complete words have matched (after successive character matches), and the program ends. Otherwise it proceeds to test the next pair of characters.

If on the other hand the two characters do not match, the program branches to *newword* at line 280. The purpose of this routine is to move along the table to the start of the next word, so that the comparison routine can be called again. When this check is being made, a special look ahead test must be performed to check for the end of table marker. This is performed in line 350. If the end of the table has been reached, the program terminates with zero in the accumulator, indicating a failed search.

In order to make this program work with a search table larger than 255 characters, we would need to use indirect indexed addressing (introduced in part 4 of the series). In this case, the compare instruction would take the form:

CMP (base),Y

The location *base* would initially contain the address of the start of the table, but each time Y reached the value zero, after the INY instruction, the top byte of the 16-bit address stored at *base +1* would be incremented by 1. This would mean that the routine could be used with tables as large as the 6502's 64K memory map will allow.

LOOK-UP TABLES

So far in our discussion of searching techniques, we have been concerned only with discovering whether or not a target byte or word is present in a data table. In many applications however, the result of a tabular search will be a value or address. In this case the table of data is referred to as a look-up table, for obvious reasons. Many examples spring to mind. A telephone book program might return with a telephone number on finding a surname match in its table, or more technically, a SIN table would return with the SIN of the target value. Or to take a final example, every time that you issue a star command at the computer, a very similar

matching process takes place. Here the look-up value which the search routine returns will be the address of the routine corresponding to the star command issued.

But before discussing this kind of look-up, I want to mention a very smart look-up technique which can be used in certain circumstances, and which avoids the necessity for searching altogether. Essentially, it uses the address offset of each item in the table as an index to the table's contents. Thus for example, if we were to create a look-up table for SIN values from 0 to 180 degrees, we could use the following in Basic:

```
FOR A=0 TO 180
  A?base=250*SIN(A*PI/180)
NEXT
```

This will place an integer corresponding to $250 \cdot \sin(A)$ at location *base*+*A* (where *A* is in degrees). To find the scaled SIN of *N* degrees, a piece of machine code would only need to perform:

```
LDY N
LDA base,Y
```

This works without the need for any searching because we have arranged the table so that the scaled value of SIN(10) is in location *base*+10 and so on.

Of course, where data cannot be indexed in this very convenient way, we are forced to perform a search before the data corresponding to the target item can be looked-up. In such cases there are usually two ways of storing the data to be returned. It can either be embedded in the search table, adjacent to the item to which it refers, or it can be kept in a separate table linked to the first. The advantage of the first method is that each search item is held next to the look-up item, but the disadvantage is that the search routine must continually skip around the look-up data at the end of each search item. In the following we will add a

number of lines to the string search program above to allow it to perform a look-up function similar to that found in ROM software for interpreting star commands. We will use separate command and address tables.

To achieve this, just add the lines given in listing 3 to those of listing 2. When you run the program you will now see that each of the words in the table, which can be thought of as a command table, is displayed with an index number. Index numbers are given as even numbers only, since they will be used to index a two-byte address, as we shall see in a moment. The result of each positive search now includes a display of the index number for the target word. If we were using this code to interpret star commands, the table would be replaced by a list of command names, and the index returned whenever a match was achieved would be used to jump (using the JMP instruction) to the corresponding piece of code.

Listing 3

```
35 REM With look-up index
50 word=&B00:table=&A00:count=&70
125 LDA #0:STA count
345 INC count:INC count
430 Z=0:N=0
460 PRINT N SPC8 Z$
465 N=N+2
565 IF Z>0 PRINT "Index=";?count
```

To make this work you would need to set up a jump table somewhere in memory, say at address *base*, and fill it with 16-bit addresses for the code for each star command. Then the following would do the trick:

```
382BEQ quit
383LDY count
384LDA base,Y:STA &80
385LDA base+1,Y:STA &81
386JMP (&80)
388.quit
```

This would execute an RTS (line 390) if no match were found, otherwise &80 and &81 are loaded with the look-up address, and an indirect jump is performed. This has the following effect: "Jump to the address made up from the two bytes stored at the following adjacent locations: &80 and &81".

Next month we will be returning to some pure arithmetic, and will take a look at routines for performing multiplication and division.

B

In this series of workshops Sheridan Williams explains how to make the most of the effects that your printer can produce. Necessarily the first article in the series is rather elementary, however future articles will cover FX3 and FX5, DIP switch settings, in-built printer buffers, configuration at power-on and more.

There are, of course, many dozens of popular printers, all quite easy to connect to the BBC micro, Master or Compact. Fortunately for once, everything shown in this series will work equally well on all Acorn's micros, including the Archimedes.

Epson printers, and the so-called Epson-compatible printers, are by far the most common category of printer. It therefore makes sense to concentrate on this range. However, for those with printers that are not Epson-compatible, this Workshop will show how to control these too. For those with daisywheel printers, the only effects that you can get are: underlining, backspace (hence overprinting), Tabs, number of characters per inch, and lines per inch, and on some printers - reverse paper feed. You cannot change the style of the characters (without changing the daisy wheel), nor are sophisticated graphics available. This series will, however, show how to obtain those effects that are relevant to daisywheel printers.

CONTROLLING THE PRINTER WITH BASIC

BBC Basic has three VDU commands that are of direct interest to us for printer control:

- VDU1 - sends the next character to the printer only.
- VDU2 - enables the printer.
- VDU3 - disables the printer.

After issuing a VDU2 instruction all output normally sent to the screen, will be directed to the printer as well (in a later article we will cover how to send output solely to the printer).

Try this example:

```
10 FOR i=1 TO 10
20 IF i MOD 2=0 THEN VDU2
30 PRINT i;" ";
40 VDU3
50 NEXT
```

This program will print the numbers 1 to 10 on the screen, but only the even numbers will be sent to the printer. Notice how (in line 40) a VDU3 is executed even when in some cases a VDU2 has not previously been issued. This does not matter at all.

GLOSSARY

ASCII is the American Standard Code for Information Interchange. The most popular code for representing characters on microcomputers. See this month's First Course for more information on the subject.

In order to implement all the special effects offered by the printer we need to understand the use of VDU1. You should note however, that VDU1 will not work until a VDU2 has been issued previously. Once VDU2 has been given, the printer stays active and all subsequent PRINT and VDU statements send their output to both screen and printer. If you wish characters to be sent only to the printer, VDU1 is what you want. Note however, that VDU1 is different, and needs to be given before *each* character that is sent to the printer.

VDU1 simply sends the next character directly to the printer without displaying it on the screen, and we need this for issuing the special characters 0 to 31 inclusive, whose effect on the screen might be disastrous. For example, character 12 would clear the screen if sent with PRINT CHR\$12 or VDU 12, both of which have the same effect. To restrict its effect to the printer (and not the screen), we issue VDU1,12 which sends character 12 to the printer only where it does the next best thing to clearing the screen and activates a **form feed**. Make sure your printer is switched on, is on-line, and has

paper in it. Now try:

```
VDU2
VDU1,12
VDU3
```

Alternatively, this can all be combined into one statement:

```
VDU2,1,12,3
```

Note how VDU commands may be strung together. After issuing this you will see a sheet of paper turned up on the printer.

Certain codes like 12 - FF (form feed), 13 - CR (carriage return), 10 - LF (line feed), are universal, and will hence have the same effect on all printers. Others like 15 (which in the table of ASCII codes is known as SI), are printer dependent. On Epson compatibles, character 15 switches the printer into condensed printing mode (17 characters per inch instead of the normal 10 ch/in); on the NEC PC-8023B-C printer you will need to send two characters to achieve the same result, namely 27 and 69.

From now on all printer codes will be given using VDU commands, and it will be assumed that a VDU2 has been given at some earlier point in the program. For example, to print in condensed mode on an Epson compatible printer you must issue VDU1,15, on the NEC PC-8023B-C you would issue VDU1,27,1,69. Notice how *each* printer code *must* be prefixed with 1. Can you see the difference between VDU1,27,1,69 and VDU1,27,69. If not try the latter and you will see that the letter E appears on the screen. This is because 69 is the ASCII code for the letter E, and as VDU1 sends one character to the printer *only*, when you omit the 1 the 'E' gets sent to the screen as well.

UNDERSTANDING THE MANUALS

Before continuing, it is essential that you can read and interpret the instructions given in the manual. So turn to the page on **Condensed or Compressed printing, or Changing the font/character size**. You must remember that the manuals are written for users of machines other than the Acorn range, and if they said "For condensed print use VDU1,15" this would be of no use to non-Acorn users. To quote from the TAXAN KP-810 manual:

SI

Condensed Mode Setting

Code: <0F>H <15>10

BASIC Syntax: CHR\$(&HF); CHR\$(15);

This is followed by a list of conditions which should be read, as it is here that the differences between printers often lie. For example, on some printers the chosen effect is cancelled when a new line is turned up, on others it

remains in force. Most manuals then go on and give various examples, which in most cases are far from clear, simply because they assume non-BBC Basic.

The most important information to extract from the headings in the manual is the characters to send to obtain a particular effect. You might as well use the base 10 values, as there is nothing to be gained from using the hexadecimal values prefixed of suffixed with an H. These decimal numbers may appear on their own, as in <15> or as Basic syntax as in CHR\$(15); in either case it is the number 15 that is required.

Armed with the knowledge that we can send the characters 0 to 127 to the printer, and that characters 32-127 produce the ordinary printable characters, we are apparently only left with characters 0-31 to achieve all the possible special effects. As there are many more than 32 special effects, how are these obtained? The answer is by means of Escape sequences.

Character 27 is the standard ASCII code for the Escape character. This is the character adopted by printer manufacturers to signal that there is a special sequence about to follow. For example, to produce underlined text the printer requires the sequence 27,45,1. To cancel this, the printer requires the sequence 27,45,0. Using the VDU1 statement this equates as follows:

```
27,45,1 becomes VDU1,27,1,45,1,1
27,45,0 becomes VDU1,27,1,45,1,0
```

Be careful: it is very easy to forget to prefix the final 1 with a 1. Try the following on your printer:

```
10 VDU2 20 PRINT"Ordinary, ";
30 VDU1,27,1,45,1,1:PRINT"Underlined";
40 VDU1,27,1,45,1,0:PRINT" Normal"
50 VDU3
```

Figure 1 is a table of the ASCII codes from 0 to 31 together with the standard abbreviations used to indicate them in some printer manuals.

	0	1	2	3	4	5	6	7	8	9
0	NUL	SH	SX	EX	ET	EQ	AK	BEL	BS	HT
10	LF	VT	FF	CR	SO	SI	DE	DC1	DC2	DC3
20	DC4	NK	SN	EB	CAN	EM	SB	ESC	-->	<--
30	^									

Fig. 1

In part two we will complete the single character codes, and cover the most common requirements of printers, namely underlining, enlarged, bold, italics, £ and characters. 

By Mark K. Sealey

This month in Beebug Education I want to look at some of the ways that the Acorn family of computers has been used in language development with pupils of all ages. The aim is to give teachers already familiar with other uses of the micro, such as maths and science, some pointers as to the way they might expand these, and to assess the likelihood of success in the light of accepted learning theory.

Suites or individual programs in this area fall into one or more of four categories. Each of these will be discussed, some suggested uses outlined, and a new example of the most worthwhile will be briefly examined.

Firstly, word processing is by now such a common use of the BBC micro that attention is readily drawn to the more specialist applications. These include both the simplification of editing techniques, for instance, to cater for Special Needs, as well as those packages (usually ROMs) that reproduce a non-standard character set such as Hebrew, Russian or one with a high concentration of scientific symbols (see also the review of Word Power in BEEBUG Vol.6 No.8).

Product Supplier	Vue-Scientific Intelligent Machines Ltd. 66 Browning Road, Bushwood Estate, London E11 3AR.
Prices	£37.50 (Draft Quality) £49.95 (Letter Quality)

Vue-Scientific is a well produced, user-friendly text processing ROM that will reproduce Greek, scientific and mathematical characters on the screen in either mode 0 or 4. It also allows normal script (like this) to appear at the same time. Once you have edited, formatted and previewed your text, you can print it out. This will either be in draft mode - which is perfectly good, as in the illustration below - or near letter quality, but you must have an Epson (or compatible) printer.

I found the variety of normal word-processing commands available quite adequate. Wordwise users will feel at home too. Markers, Find and Replace, word-counts etc. are all possible, using the function keys. Superscript and subscript are easy to obtain as well. This good package (with equally good documentation) should be a boon to anyone in a secondary school, or a college or university maths or science department, who needs to produce documents, essays or lecture notes using these symbols.

The chemical equations are composed as follows:

The Navier-Stokes differential equations are:

$$\rho \left(\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = -\frac{\partial p}{\partial x} + \mu \left(\frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 v}{\partial x^2} \right) + X$$

Product Supplier	'Prompt' and 'Writer' Micro Electronics Support Unit Unit 6, Advanced Technology Building, Sir William Lyons Road, Science Park, University of Warwick, Coventry CV4 7EZ. £3.00 (inc VAT) for one pack containing both.
Price	

At that price, how could you fail? MESU's best efforts have gone into upgrading these two excellent starter word-processors, Prompt being just that little bit easier to use than Writer. The use of menus and colour is admirable, the display a model of clarity and the documentation outstanding. True, these are aimed at Special Needs, and those involved in the development of the package are experts in that field, yet there is a versatility and flexibility that should make this suite a standard for children in infant, special schools and adult literacy classes. It includes utilities, support materials (such as A4 and A3 Concept Keyboard overlays and support of Votrax and Namal Speech input devices) as well as useful suggestions in the manual.

Secondly, there are those programs designed to sponsor some activity where language is important. One of the most influential, and still most popular classics, is Podd (from A.S.K. - take a look if you've not already seen it). Its success lies in the educational theory behind it.

Instead of expecting children to respond in one way only to a given stimulus or cue, it encourages child-centred exploration, recognizing that there are as many ways of reacting to a situation as there are children! When all is said and done, the major pedagogical texts agree that language is concerned with meaning. Chopping it up into artificial components cannot work: it needs to be used. Such open-endedness is also the strength of the latest offering from Topologika, "Giant Killer".

Product Giant Killer
Supplier Topologika
P.O. Box 39,
Stilton,
Peterborough PE7 3RL.
Price £16 (B, B+ and Master)
£18 (Compact) excl. VAT

This is the very best of its kind. Although most of the activities are mathematical ones, it is the co-operation and discussion by a group of children that actively enhances the quality of work being done. Here, a superior and very well thought out adventure (loosely based on the infamous beanstalk) encourages progress through all sorts of puzzling and worthwhile locations and situations. Maps are particularly important, and there are exemplary worksheets, children's and teachers' notes to go with it. If you haven't used this type of program with pupils before, this is as good a place to start as any.

Many teachers and educational users have long believed that almost any activity that promotes focused discussion will lead to enhanced learning, since the accommodation and assimilation of new ideas can be accelerated by articulating them. For this reason, you may judge how much the software that you use actually promotes discussion on and off the computer.

Thirdly there are those programs that aim to teach a particular aspect of language such as spelling or grammar. These are the least satisfactory in my opinion. This is because they often rely on memory for their success, or employ methods of reinforcement based on the

now surpassed psychology of stimulus-response. They frequently fail to distinguish at all between spoken and written language, which is a distinction that all specialists assert to be vital.

Lastly there are programs written to allow practice in (mostly) European modern languages. Unless they can claim to surround the user with a consistent "micro-world" or predictable environment of Spanish, German or whatever, there is the danger that there will be continual reference back to English.

I stand by the contention that only when the user is fully in control and able to determine where a program is going, can using the computer be superior to not using it. I'll end on a positive note with a superb example of the second activity identified earlier. Let your imagination go; fulfill your wildest dreams; spend time off the machine planning. Manage and run a pop-group!

Product Tycoon
Supplier Cambridge Micro Software
The Edinburgh Building,
Shaftsbury Road,
Cambridge CB2 3RU.
Price £27.50 (excl. VAT) for B, B+ or
Master with double disc drive

This too, is exemplary. The game is of the adventure type - with a healthy mix of simulation. You choose a personality for yourself and then a job; guide the group you have chosen through the hurly-burly of the entertainment world. If you are lucky, you'll meet and use lots of ideas and different registers of vocabulary on the way. The aims of the program are quite clearly set out in the front of the attractive notes that go with these discs. The subject-matter will be appealing to many pupils of 14 and upwards, at whom the package is aimed, and because that real environment in which things behave as you would

expect is achieved from the outset, taking part with all the attendant decisions is pleasurable. There is no drilling, no wrong guesses and no expected answers. As a result, it works. **B**

Peter Coaker has produced a cracking good implementation of card Patience in one of its oldest and most popular forms. But be careful, it's surprisingly addictive.

The game has been split into two separate programs so that it will work on the model B as well as on the Master. Unfortunately the listing still needs to be rather compact, so try not to insert too many spaces when typing it in. Type in the two listings and save them separately to tape or disc. Be sure to call the second program 'PAT2' so that it will be chained correctly by the first. When both listings have been entered and saved, run the first program. If PAGE is above &E00 you will have to wait while the entire program is moved down automatically to &E00. The cards will then be shuffled ready to start.

Initially the cards are laid out in seven columns, the number of cards in each column increasing from one to seven. Only the first card in each column is exposed, the others are laid face down. The exposed cards are laid on the first 'face down' card in the row above.

The ultimate object of the game is to assemble four stacks, one for each suit, with all the cards in order from the Ace upwards. Each stack must therefore be started by putting out any exposed Ace. Subsequent cards of the same suit, in ascending order, are put out as they come to the bottom of the columns. To expose the hidden cards, cards may be moved from one column to another, provided that they are in descending order, with red cards on black, and black on red. Groups of cards, in black-red-black sequence and in descending order, can be moved in blocks from one column to another.

When no further moves can be made, the deck of 24 remaining cards may be used. The deck is placed face down on the table. Three cards are

turned over at a time, the third being exposed. If this card can be put out, either to the stacks or to the columns, this should be done. Rules of sequence and colour still apply. Once the exposed card on the pack has been removed, the card that was underneath it and now exposed may be used. If this card cannot be used, another three cards may be turned over and the third card exposed in the normal manner. When the deck has been turned completely, the bottom card is put on the top of the deck and the process repeated until no further moves can be made in three cycles of the deck.

The rules may seem a little daunting when written down but, as ever, the easiest way of becoming familiar with the game is to play it. All moves are checked for validity, aces are automatically sent to stacks, stacks are removed from the table when the King is reached, and the computer will detect when it is not possible to finish the game.

The cards are easily moved around the table using single key presses in most cases. The computer will ask you the column from which cards are to be moved, the number of cards to be moved, and the destination column. You will also be given the option of shuffling the pack and using the exposed card. Everything else is completely automated.

This is a good old game of Patience, very well implemented on the micro, and you are sure to be impressed at just how often you go and play it. Why, next time you might well win.

INVISIBLE CALCULATIONS

Ian Bishop

When arranging large spreadsheets with Computer Concepts' Intersheet, it is often convenient to hide intermediate calculations so that they are not displayed with the rest of the results.

To hide such calculations, use the hold facility (/H) to place blank rows or columns over them. It is then possible to reduce the column width to three characters. This will replace the intermediate calculations with blank rows or columns. Remember to answer YES to the question 'Print held lines?' when the sheet is to be printed.

COLOUR VIEW

Graeme Davidson

Although the original View guide explains how to redefine the foreground and background colours in View (all modes except 7), no mention is made of it in the documentation supplied with the Master, and in any case the technique is often overlooked. The foreground and background colours can only be changed from within Command mode. The format of the command is as follows:

Ctrl-S followed by ab000 where 'a' represents a logical colour in the selected mode (foreground or background). For example, in the commonly used mode 3, 'a' would be 0 to change the background, 1 to change the foreground. The

letter 'b' represents the physical colour that you want. A complete list of physical colours can be found in your User Guide. For example, to change the background in mode 3 to blue (colour 4) type: Ctrl-S 04000.

BASIC PRIORITY ON THE B+

Neil Stephens

On the BBC model B machines and the Master series the language which the machine enters upon a Reset or power-up can be easily defined, either by physically changing the order in which the ROMs are plugged in for the former, or by using the *CONFIGURE LANGUAGE command with the latter. Unfortunately neither of these two methods can be used on the BBC B+ because the *CONFIGURE command is not implemented, while Basic and the Operating System are both contained in the same chip.

Fortunately Acorn have provided a link to alter the logical ROM position which Basic occupies. Altering link S13 into the North position will make Basic resume the lowest priority position. The first language ROM encountered in a high priority socket will then be entered upon power-up.

POWER-UP CONFIGURATION

Brian Stein

Towards the righthand front corner of the keyboard PCB there is provision for an eight-

way DIP switch to be fitted. If the switch has not already been installed, one can be obtained from most electronic shops (inc. BEEBUG) and soldered in relatively easily. This switch determines various options set upon power-up or after a Break.

As you look at the bank of switches they are numbered 0 to 7 from right to left. Switches 0, 1 and 2 determine the screen mode, and this is represented by an inverted binary value between 0 and 7 (i.e. 101 would select screen mode 2). A switch in the up position represents 1, in the down position 0. Switch 3 reverses the effect of pressing Break and Shift-Break. In this condition the computer will boot the disc in the drive upon power-up. Switches 4 and 5 effect the disc drive speeds. These settings were covered in last month's Hints and Tips page. The last two switches, 6 and 7, are not used.

DOUBLE STEPPING

Micky Harford

For those people using 1770 disc interfaces, the *DRIVE command has been extended so that forty or eighty tracks may be specified. This means that forty track discs may be read on eighty track drives without the use of a hardware switch. The format of the command is:

*DRIVE n t
where n is the drive number and t is 40 or 80.

MASTERING THE KEYWORD GENERATOR

Having recently upgraded from a B to a Master, I found that the Keyword Generator program (BEEBUG Vol.3 No.6) only produced garbage. I was able to determine that the following alteration to line 370 enabled the program to work as before. I trust this program may be of help to others who use this program to ease the tedium of inputting Basic programs.

```
370 LDA#&56:STA&80:LDA#&84:
    STA&81:LDY#0
```

B.P.Weller

We are always interested in publishing amendments to older BEEBUG programs to enable them to run on the Master and Compact.

SINGLE KEY AUTO-SAVE

Although I do not want to detract from the merits of the Auto-Save utility in BEEBUG Vol.6 No.2, I find the following single key press even more useful, particularly if I am called away from the machine in a hurry. The only rule is that the first line of the program under development should be a REM statement with one space followed only by a five letter name and a one digit number plus a space, or a two digit number.

The key (f0) then inserts the next number into line one of the program, saves it under

that name and number, and also saves a copy under the name LAST. In the IBOOT file of my development disc I arrange to LOAD"LAST" which immediately puts me back into business when I can get back to the computer. I think your readers would find this useful.

```
*K.0$(PA.+11)=STR$(VAL$(PA.
+11)+1)|Msave$=LE.$(PA.+6),
7)|MSA.save$|MSA."LAST"|MP.
$(PA.+5)|M
```

Francis W.Aries

DISC MANAGER BUG

I have been using the disc Manager from Vol.5 No.4 for some time and have found it extremely useful. Unfortunately there is a bug in the Rename option if an attempt is made to rename a file on other than drive 0. The problem can be overcome by changing line 2670 to read:

```
2670PROCos("RENAME ":"D$+"
"+name$(n)+" ":"D$+"."a$a:na
me$(n)=a$:ENDPROC
```

D.G.Beecham

It was only intended that Rename should work with drive 0, so this is a useful improvement.

IMPROVED KEYSTRIPS

With reference to Tony Briselden's letter in Vol.6 No.5 I would like to suggest the following additional changes to the Keystrip Generator (Vol.6 No.4). This amendment prints the legends in double

strike (line 2145), and the keystrip title in double-width characters (lines 1825 and 1835) on an Epson compatible printer. Add the following lines:

```
1825VDU27,64,14,27,69,27,71
1835VDU27,106,12,27,64,27,
    51,24
2145VDU27,71
```

D.J.L.van den Bergh

MS-DOS TO BEEB

I would like to suggest an idea for a program to be published in BEEBUG, one which I think may be of general interest to BEEBUG readers. Many of us who work in offices and elsewhere have access to PCs or similar during business hours using discs formatted to MS-DOS standard. My plea is for a program which would enable my BBC B to read a PC disc so that wordprocessor text could be transferred to my Wordwise at home.

Similarly, after amending the text at home, I would like to re-write the file back to a disc in PC format for use back in the office.

John Tupper

We have investigated the possibility of this and it certainly seems feasible. Even now one of our freelance contributors is working away to produce just such a utility which we hope to publish in the April issue of BEEBUG or soon after.

CONTRIBUTING TO BEEBUG PROGRAMS AND ARTICLES

We are always seeking good quality articles and programs for publication in BEEBUG. All contributions used are paid for at up to £40 per page, but please give us warning of anything substantial that you intend to write. A leaflet 'Notes to Contributors' is available on receipt of an A5 (or larger) SAE.

Please submit your contributions on disc or cassette in machine readable form, using "View", "Wordwise" or other means, but please ensure an adequate written description is also included. If you use cassette, please include a backup copy at 300 baud.

In all communication, please quote your membership number.
